AGRANULOCYTIC ANGINA—A GENERAL DISCUSSION OF THE DISEASE AND TREATMENT

By BEECKMAN J DELATOUR, M D, NEW YORK, N Y.

OUR first knowledge of agranulocytic angina comes to us through Werner Schultz in Germany, who discovered an apparently new syndrome which is described by A Leon in August, 1923, and he states that Schultz has since discovered five other such cases. In a paper published by W. Schultz and L Jacobowitz in October, 1925, they had encountered to date ten cases of agranulocytic angina and regarded only thirteen other cases in the literature as belonging to the category. Dr. J H Skiles, in January, 1925, reports a case and refers to an article by Dr. Beatrice R Lovett in the *Journal of the American Medical Association* as the first case described in America. Dr Lovett, before describing her case, remarks on the findings from reports of cases made in Germany and from her case draws a similarity to the symptoms of those previously described. Since these dates there has been a great deal in the literature about agranulocytic angina which seems to be generally accepted as a clinical entity. It should have an essential foundation for its characteristic blood picture, namely a marked reduction in the leukocytes and almost an absence, or extremely low percentage, of granulocytes. This, with a close similarity in the symptoms and pathological changes of the many cases described, permits a classification under the name of the blood picture and angina. In an article in the Bulletin of the Johns Hopkins Hospital for 1930 on Recurrent Agranulocytosis, it is stated by the writers, "Within the last several years the literature on agranulocytic angina and on agranulocytosis in general has become voluminous." This is very true. How strange it is that more had not been written on this subject long before, and not left to just these recent years, when careful studies of the blood were in existence long ago. It is unlikely that it is a new disease since 1922 or that recently new etiological factors have come about to produce it.

I have collected thirty two distinct cases described in the literature as agranulocytic angina besides five cases that have occurred in St Luke's Hospital, New York, and one reported to me by Doctor James R Scott in his practice, and one

case of my own of agranulocytosis without angina, following pneumonia. In 1927, V. Weiss in the *Zeitschrift für Klinische Medizin* reports 41 collected cases, and in 1928 C Aubertin and R Levy in the *Archives des Maladies du Cœur* report fourteen similar collected cases to the one they describe as agranulocytic angina, and U Friedemann in 1928 in the *Zeitschrift für Klinische Medizin* reviews 29 cases of the same. All this shows there has not been a scarcity of material in recent years for the compilation of facts.

There has not been any etiological factor proven in the decrease in leukocytes and granulocytes and the accompanying clinical syndrome. G Blumer, in the *American Journal of Medical Sciences*, in 1930, showed there are cases of local and general sepsis with an agranulocytic blood picture aside from the recognized group of agranulocytic anginas, and states that it is not clear whether the sepsis or the loss of power of the bone marrow to form granulocytes is the primary lesion. N Christof, in the *Wiener Klinische Wochenschrift* for March 14, 1929 reports a case of pyoderma two weeks after birth, and two weeks later hemorrhagic gastro enteritis and suppurative adenitis, and tonsils swollen and red without membrane or pus. The child recovered completely after several weeks. Christof believed the case was due to a streptococcus which was cultured, and states the study of the case proved that agranulocytosis is not a disease sui Generis, but rather a symptom of generalized infection. Dr Eugene C Plette, from observation at necropsy of Dr Skiles' case (reported in the *Journal of the American Medical Association* of May 9, 1925) noted a marked development in the cytoplasm of the sinus endothelium and an increase in the size of the reticular cells. Also bacterial emboli were found in capillaries of the liver, and in the cortex of the kidney, and some in the medullary substance. In the stomach a number of superficial foci of necrosis penetrated in places as deep as the muscularis mucosa. Gram stain of the ulcers showed gram positive streptococcus and staphylococcus and gram negative bacilli. He believes the necrotic changes made conditions favorable to a mixed in-

tion. He thinks these ulcerations were evidently due to bacterial emboli that had occluded the corresponding vessels, and further suggests the mouth lesions and ulcerations in the vagina of this case were due to bacterial emboli and were secondary lesions as a consequence of the septicemia. He states that they were unable to obtain a positive culture and thus identify the causal organism. Morphologically, they were gram negative in paraffin sections, two to four microns long, and about one micron thick, with rounded edges.

Sachs, in 1928, reported a case in which a pure culture of streptococcus was obtained from the throat of the patient. L. K. Gundrum in March, 1928, in the *Archives of Internal Medicine* reported a patient with agranulocytic angina. He states that at necropsy a pure culture of *B. coli* communis was obtained from the heart's blood and from the cervical lymphnodes. U. Friedemann, in the "Deutsche Medizinische Wochenschrift," December, 1927, on a paper on healing following roentgen irradiation of the long bones in four cases of agranulocytic angina, thinks it probable the disease is not an infection but originates in endogenous disturbance, perhaps of endocrine nature. H. L. Dwyer and F. C. Helwig in the *American Journal of the Diseases of Children* for 1928 report a case under observation for anaemia with enlarged salivary glands and spleen, that developed Vincent's angina, leukopenia, and a loss of polymorphonuclear cells in the blood. At necropsy, bacterial emboli were seen to have invaded the heart muscle, liver and kidneys.

In May, 1928 in the "Zeitschrift für Klinische Medizin" Berlin, U. Friedemann published an article on twenty-nine cases of agranulocytic angina. In 26 cases blood cultures anaerobic and aerobic were taken. In twenty cases the blood was negative, the streptococcus was found twice, the pneumococcus, staphylococcus, pyocyanus and colon bacillus one each.

J. Zikowsky, in the "Wiener Klinische Wochenschrift," Vienna, July, 1928, reported two cases in which streptococci were found in the blood. Herbert W. Dasse (in the *Journal of the American Medical Association*) in December, 1928, reports a case similar to that reported by Doctor Werner Schultz in 1922, in which almost a pure culture of *B. pyocyanus* was obtained from the throat. He also stated that injections of *B. pyocyanus* were made subcutaneously into guinea pigs and produced a slight reduction in the leukocytes and always a relative reduction in the granulocytes. A local ulcer formed at the site of inoculation, with a center of necrosis and slight inflammatory border. W. Schultz reported a case in 1927 with recovery in which the tonsillitis appeared late, which he states speaks for the theory that the tonsil is only a point of localization of the disease and not a portal of entry. Two cases were reported by G. J. Kastlin among 43 cases reviewed in the *American Journal of Medical Sci-*

ences. He says that the differential diagnosis in agranulocytic angina presents points similar to the reaction to specific poisons, lymphatic leukaemia, and cases of sepsis with leukopenia, and that it does not fall within the classification of these conditions but with the evidence at hand it cannot be called a clinical entity.

Joseph A. Moore and Henry S. Wieder in the *Journal of the American Medical Association* for 1925 report a case which showed staphylococci in cultures from the mouth and tonsils. Dr. Beatrice R. Lovett reports in the necropsy of her case that large numbers of bacteria, all gram negative, of different forms and sizes, infiltrated the necrotic tissue to the deepest parts. Also, *B. pyocyanus* was cultivated from the lesions in the throat and vagina after death. This, and a pneumococcus, were obtained from cultures in the spleen. Experiments on guinea pigs were made by intra-peritoneal injections of broth cultures of *B. pyocyanus*, containing an exudate. It had a toxic effect on the leukocytes, producing vacuoles and irregular staining. In July, 1929, in the *Missouri State Medical Association Journal*, J. C. Kopelowitz, in reporting a fatal case of agranulocytic angina, says that he does not believe agranulocytic angina is a distinct angina. He feels that there must be some factor, allergy, or possibly endocrine factor, that renders the haematopoietic system susceptible to a noxious agent. Leon Bromberg and Paul Murphy, in the *Journal of the American Medical Association*, describe a case following 12 days after the first injection of dead typhoid bacilli for prophylaxis, and four days after the second injection took place. They suggested in this case that the agranulocytosis may have resulted from an overwhelming foreign protein reaction in a sensitive individual. Of the five cases at St. Luke's Hospital, New York and the sixth of Dr. James R. Scott, the throat cultures obtained showed a variety of organisms — staphylococcus, streptococcus, streptococcus haemolyticus, non-haemolyticus and viridans, also Vincent's organisms. Only one case showed a positive blood culture, and that was a streptococcus haemolyticus. From the evidence at hand, nothing gives sufficient proof to attribute the disease to any one particular organism. As cases of agranulocytosis have been reported with ulcerations in other parts of the body than the tonsils or pharynx, it seems unlikely that the tonsils are necessarily the portals of entry. In Bromberg and Murphy's case a sore throat developed 12 days after the first injection for typhoid prophylaxis, and five days later occurred an ulceration with a necrotic base around the left upper molar, and a pustule of the right nasal orifice with cellulitis, a necrotic ulcer on the hard palate, and induration of the left major labia. This case showed almost a complete absence of granulocytes, and two eosinophiles. It was suggested from this the granulocytosis may have resulted from an overwhelming protein reaction in

a sensitive individual. It seems likely any bacterial protein could be responsible for producing such a condition in the blood when there is a susceptible bone marrow.

In the histopathological report of Eugene C. Piette on the case of Dr. James H. Skiles, which showed ulceration in the stomach and cervix as well as the throat and gums, enormous development was found in the sinus endothelium of the spleen. In some of the sinuses small masses were found which, when stained, proved to be mycotic emboli. Numerous bacterial emboli were found in the cortex of the kidney and some in the medulla. In the outermost liver of the necrotic focus of the ulcers of the stomach, gram stain showed gram positive staphylococci and streptococci. In this case it was suggested the mouth lesions and vagina and stomach were due to bacterial emboli, and were secondary lesions as a result of the septicaemia. In a case not included in this series of six I am reporting, a woman had had a mild jaundice for six months. She developed a pneumonia which had almost entirely cleared up, but with it a typical picture of agranulocytosis, very little anaemia, no reduction in the red blood cells, white blood cells ranging from 2,900 to 3,400 and polymorphonuclear leukocytes from 4 to 8%. She died in convulsions and had several attacks of haematemesis the day of her death. No ulcerations were found at necropsy. There was a subacute yellow atrophy, a haemorrhagic condition of the entire gastric mucosa and the oesophageal veins and the anastomoses between the mesenteric and parietal veins were greatly dilated. Very likely, the septic condition of the pneumonia had an action upon the bone marrow in depressing the granulocytes but did not result in ulceration or sore throat.

The disease, as first described, was said to occur in middle aged and old women starting in suddenly with high fever and general malaise soon followed by ulcerations and gangrene affecting always the pharynx (especially the tonsils) sometimes the tongue, larynx and vagina. The disease ended fatally in 3 to 14 days and the bone marrow did not contain leukocytes or myelocytes. As many more cases have come to light we see they are not limited to women and no age is exempt. Of 29 cases reviewed by Friedemann 5 were men and 24 women. Undoubtedly, the most frequent site of ulceration is the pharynx and mouth, but many other locations have been affected. I have found no record of ulceration of the colon and small intestine. Skin ulcerations have been reported, and ulceration of the vagina, vulva, and anus are not uncommon. Robert W. Buck of Boston reports a case of agranulocytosis where the only lesion that was found was an indolent ulcer of the anus. Of the six cases I report there was ulceration and gangrene of the tonsils or pharynx, or both, in four and redness and oedema in the other two cases. Two showed

enlarged cervical glands and one enlarged salivary gland with suppuration. As to duration of the disease, it varies, although if death occurs it is usually rapid. Of these six, one died on the second day and the others on the sixth, eighth and thirty-sixth day. The one dying the second day had a positive blood culture of streptococcus haemolyticus. The two other cases recovered. All but one of the cases ran temperatures from 103.8 to 106°F. That of Dr. Scott's was normal until a few days before death, when the temperature reached 102°F.

Jaundice has been described in a number of cases by different writers. The only one I have seen is the case I have mentioned of acute yellow atrophy. It is generally accepted that the disease is without haemorrhagic diathesis, and although a number of cases show a marked secondary anaemia, anaemia is not an outstanding feature. In some cases the erythrocytes have been increased. The platelet count is normal or slightly increased, which was found in all 29 cases of Friedemann. The outstanding feature of the blood count in the disease, and of the disease itself, is the leukocyte count and the granulocytic reduction. This, of course, is outstanding in all the case reports and is a necessary factor in the diagnosis. The lowest count in each of these six cases ranged from 525 leukocytes to 1,300 and granulocytes from zero to 16%. One case of 600 leukocytes and 4 granulocytes, and another of 1,100 leukocytes and 2 granulocytes, recovered. Lovett shows in her case that leukocytes on an average of four counts reached only 900 and never rose above 1,350. The bulk of the white cells were lymphocytes but with a high percentage of plasma cells 37%. Polymorphonuclear leukocytes were always below 5%. From absolute counts it appeared the reduction affected the lymphocytes as well as the granular cells but, of course, to a less extent. Blumer draws attention to the difficulty of diagnosis in cases of local and general sepsis with an agranulocytic blood picture, aside from the recognized group of agranulocytic angina, and says it is not clear whether the sepsis or loss of power of the bone marrow to form granulocytes is the primary lesion. Such cases, he says, cannot be differentiated clinically from acute aleukaemic lymphatic leukaemia with terminal infectious processes, and in some instances he says it may be difficult to differentiate between aplastic anaemia with terminal infection. On the other hand, Moore and Wieder comment on the differential diagnosis from aplastic anaemia, aleukaemic leukaemia, monocytic angina and septic angina and septic processes, by its frequent occurrence in middle aged women, absence of pallor, absence of marked anaemia, lack of haemorrhagic tendencies and a normal platelet count. And further, in the bone marrow, absence of neutrophils, myelocytes, myeloblasts, and the presence of erythro-

tes, erythroblasts and megacaryocytes are conclusive evidence of the disease.

Aubertin and Levy, on the agranulocytic syndrome of 14 cases from the literature, speak of the absence of (1) Important modifications in the number and quality of the erythrocytes and blood platelets, (2) Signs of haemorrhagic diathesis, (3) Metaplasia of the haematopoietic organs, (4) Common mechanisms of defense about the ulceronecrotic lesions, and characterize it by the presence of (1) A marked predominance in the female sex, (2) A severe infectious condition, (3) Ulceronecrotic lesions which are usually most marked in the bucco-pharyngeal mucosa, (4) A slight or intense icterus in the majority of the cases, appearing any time during the evolution of the process, (5) Marked leukopenia with similar disappearance of polymorphonuclears, (6) Course almost always fatal in a short time, (7) An alteration in the bone marrow, characterized essentially by the disappearance of granular white cells.

Of our six cases, four were females. Only one case was below 59 years. All showed an angina or stomatitis or both. Two showed only inflammation and oedema of the pharynx, the others ulcerations of the mouth, trachea, or tonsils, and gangrene of the pharynx in two. Four cases showed cervical adenitis and one swelling of the salivary glands. Two cases were complicated by pneumonia, one of these had a large sacral abscess, the latter case recovered. One case had a cellulitis around the ear with suppuration of the submaxillary gland and this, too, got well. The pneumonia that recovered showed an anaemia of a moderate degree and recovered from the agranulocytosis in one month. One other case showed a very slight anaemia, and the other four cases none at all.

A number of cases of recurrent agranulocytosis have been reported. R. H. Rutledge, O. C. Hausen-Pruss and W. S. Thayer, report a case of 20 years of age presenting a cyclic agranulocytic angina, beginning at the age of two and one-half months and recurring at intervals of approximately three weeks during his entire life. They found during the height of the attacks a large number of large mononuclear and transitional cells present in the blood and during the last two days of the illness, which lasted from 6 to 10 days, immature myeloid cells appeared. The red blood cells seemed unaffected and their number per cubic millimeter and haemoglobin remained normal. They mention a slight increase in the eosinophilic leukocytes. This case also showed as the commonest physical manifestations, a sore mouth with swelling and reddening of the gums, and shallow ulcerations of the gums, tongue, and buccal membranes, and lips, associated with a moderate degree of regional adenitis. L. K. Gundrum reports a case of a patient that died, that had had two previous at-

tacks. Dr. Minot is reported to have seen instances of recurrent agranulocytic angina with as many as four attacks, never more. In 29 cases reported by Friedemann, three recurrences took place. In one, the recurrence that took place six months after the first attack, proved fatal. Joseph A. Moore and Henry S. Wieder gave a case with two attacks, two years apart. The patient in this instance died the 16th day of the disease.

As to the pathology of the disease the findings are variable, but with definite outstanding features. Included in the etiology, description and course of the disease, the inflammation of the mouth and pharynx with ulcerations, and ulcerations in the gastro-intestinal tract, skin, and mucous membranes, have been discussed, also the association of bacterial emboli. It would seem that the ulcerations are more liable to occur in places that are exposed to trauma. In one of our cases that recovered, the duration of the disease being 28 days, a large abscess developed over the sacrum, as well as deep ulcerations of the tonsils. Regional swelling of the lymph and salivary glands frequently occur, and sometimes suppuration. Several authors report increase in the size of the spleen and liver. In one of our six cases an autopsy was obtained, and this showed an enlarged spleen with the characteristic swelling of acute infection. In the autopsy described by Piette, mention has been made of the enormous development of the sinus endothelium of the spleen (Irritation of the reticulo-endothelial system) at the expense of the lymphatic tissue. Not a single polymorphonuclear leukocyte was seen in the spleen or any other organ. Cytoplasm of the sinus endothelium was greatly developed and many mitoses present. In the liver in some places were seen diffuse perivascular lymphatic infiltration, while the capillaries and lymphatics were somewhat distended. In the liver, spleen and kidneys bacterial emboli were seen. Degenerative changes were found in the cells of the kidneys but no inflammatory changes. One writer reports cloudy swelling of the viscera with no changes in the bone marrow, but from the evidence gathered here it would appear there is an alteration in the bone marrow, characterized essentially by the disappearance of the granular white cells and their precursor, or that they are greatly diminished, while the lymphoid and red cell forming elements are slightly, if at all, reduced. Megacaryocytes have been present. Friedman, in his fourteen autopsies, states that erythroblasts and megacaryocytes were present in normal number. In three cases there was fatty marrow, and in seven cases red marrow, and in four cases the information was lacking. He also states the spleen, liver, and lymph glands were normal macroscopically and microscopically.

As to complications, pneumonia has not infre-

quently been mentioned. Abscesses and suppuration of the lymph and salivary glands have been brought in as in association with neighboring infected or ulcerated foci. One of our cases, that died on the 8th day of the disease, showed old pinhead purpuric spots over the lower extremities. Thrombo-poenic purpura is described by a number of authors as occurring quite frequently in the disease.

There is no doubt that agranulocytic angina presents a very grave outlook. But since the early descriptions by Schultz and Leon, with the increasingly large number of cases reported, it would seem to be of a much lower mortality than was first supposed. Leon, in speaking of Schultz's discovery of an apparently new syndrome in 1922, states in 1923 that he has since observed five other cases, and says that the disease ended fatally in 3 to 14 days. Of the 29 patients studied by Friedman, in half the cases that died death occurred within the 8th day. The mortality of the total number of cases was 21.06 per cent. The outcome of 32 separate reported cases I have investigated was 20 deaths and twelve recoveries. Adding to this the two recoveries and four deaths of the present reported series gives a percentage mortality of 58.3%. From the observation of our own cases and those reported by others, as well as their opinions, it seems that the fatality of the disease is greatly enhanced by extensive ulcerations and gangrenous necroses.

There is nothing to show, from the literature that has been reviewed, that there is any outstanding or specific therapy for agranulocytic angina. As one author emphasizes, who reported two cases of agranulocytosis that recovered without any special blood treatment, that as therapeutic measures are successful only in a small number of cases, despite this, as agranulocytosis is usually a grave condition, all therapeutic measures should be attempted, especially blood transfusions and radiotherapy. In 1927, Friedemann reported four cases treated with roentgen ray irradiation of the long bones, all of whom recovered, and in his review of 29 cases in 1928 he mentioned five cases that recovered. Walters and Firor in the Johns Hopkins Bulletin for May, 1931, draw attention to two cases reported later by Friedemann that survived irradiation of the long bones, and four which resulted fatally. These men point out that Friedemann has recently reported a series of 43 cases most of them treated with roentgen irradiation. Twenty-three of the patients died from complicating sepsis, and five within thirty-six hours after irradiation. Of the remaining fifteen uncomplicated cases, thirteen were reported as cured. They suggest it is possible that irradiation may aid in the formation of new bone-forming tissue in the long bones. Their experience has been limited to five cases. Four of them, treated from June

to November of last year, are still living. The fifth case treated by them was in extremist condition and in an institution where modern therapeutic measures were not available, and died two days following the first treatment. They say it is impossible to find the role played by the x-ray as all these patients had had other types of therapy, but they feel that the results of irradiation of the bone marrow in agranulocytic angina justify a trial with such therapy when necessary.

Dr. Louis F. Hamburger, in an article on the same subject and in the same number of the Bulletin, also advocates the cautious irradiation of the skeleton by an experienced roentgenotherapist.

Wyatt, in reporting the first case at the Peter Bent Brigham Hospital in 1928, states that despite the low leukocytic count (1,800), the case recovered without any attempt at specific therapy, aside from surgical drainage of the various localized areas of infection. It is not within the purpose of this paper to go into the local treatments of our cases, except that local drainage was necessary in several. Peroxide of hydrogen, sodium perborate, and peroxide of hydrogen with Fowler's solution, were used, and throat irrigations of hot saline. L. M. Plab, Vienna, observed in a case of his, a man 31 years old, that blood transfusion had no effect on the rapid decrease of white blood cells.

T. N. R., one of the present cases under consideration, received his first transfusion of 500 c.c. of blood (Linderman method) the 7th day from the initial onset of the disease, the 2nd on the ninth, and the 3rd on the eleventh day, when the blood count the previous day was 700 white blood cells and the polymorphonuclear neutrophils 20%. The day following the third transfusion the white blood cells were 850 and the neutrophils 24%. The fourth day the white blood cells and neutrophils had risen to 3,500 and 42% respectively. The fourth transfusion took place the 16th day of the disease and two days following the white blood cells were 5,300, the polymorphonuclear neutrophils 76%, lymphocytes 22% and myelocytes 2%. Myelocytes first appeared in the blood picture to the amount of 8% two days after the third transfusion and persisted up to the fourth day after the fourth, and last transfusion. The patient was at no time anaemic. The temperature reached normal and remained there on the 23rd day after onset. The blood persisted in its normal course and the patient left the hospital forty-eight days from the beginning of his first symptoms.

A. J., a woman aged 59, with deep ulcerated tonsils, complicated with pneumonia, presented a white cell count of 600, with polymorphonuclear neutrophils 4%. Two days later a transfusion of 500 c.c. of blood was given, and the following day the leukocytes were 1,100 and polymorphonuclear neutrophils 5%. On this same day, liver

tract, one ampoule five times a day, was started. Two days after transfusion the leukocytes and polymorphonuclear neutrophils were 2,100 and 2% respectively, and five days after 6,600 and 8%. Three days after the 2nd transfusion, the leukocytes rose to 12,800 and the polymorphonuclears to 76%. This case records no myelocytes after transfusion. Six days later the full count was red blood cells 3,550,000, haemoglobin 69%, white blood cells 20,400, polymorphonuclear neutrophils 89%, eosinophils 1%, lymphocytes 4%, and large mononuclears 6%. There is a very noticeable change as to the reaction of the leukocytes and granulocytes. This high leukocyte count may be explained by the broncho-pneumonia or sacral abscess, or both, that persisted after the bone marrow had begun to react to infection. This patient showed a moderately well-marked anaemia. She recovered from her granulocytosis one month from the onset of her disease. These two cases show at least an association, with the rise in granulocytic reac-

tion and transfusion, and the reactions in the two cases are similar. In the first case there was little response to the first transfusion but, after the third transfusion two days later, there was a very definite rise in the granulocytes and the first myelocytes appeared. In A. J., the second case, the rise in granulocytes came two days after the first transfusion.

A third case treated with transfusion died the following day, and undoubtedly the transfusion was too late in this case to judge of its efficiency as to causing a response of the myeloid-forming cells.

The three of our remaining cases did not receive transfusions. One died the day the agranulocytosis gave its first evidence. Another was given Squibb's leukocytic extract subcutaneously every day and stopped after nineteen treatments. It was quite apparent that this extract had little, if any, effect upon increasing the number of granulocytes. Of these six new cases, three were treated with transfusion. Two of them lived

TABLE OF SIX NEW CASES REPORTED—Continued on page 7

Name	Sex	Age	Duration Disease be- fore enter- ing hospital	Mouth and Tonsils	Skin and other ulcerations	Glands	Outcome
B. S.	Male	21	4 days	Ulceration of al- veolar margins. Tonsils and an- terior pillars gan- grenous.	Old pinhead purpuric spots on lower ex- tremities.	Tonsillar nodes swollen.	Died 8th day of disease.
T. N. R.	Male	62	5 days	General redness of whole pharynx.		Swelling left salivary gland.	Recovered com- pletely 13th day.
A. J.	Female	59	28 days	Deep ulceration of tonsils (3 days be- fore admission to hospital)		Enlarged sub- maxillary nodes	Recovered of agranulosis in about 1 mo.
L. M.	Female	73	Symptoms developed in hospital	Autopsy. Trachea dark and red with greenish membrane on mucosa. In right pyriform fossa, on lateral wall, a small ulcer. Spleen enlarged, showing character- istic swelling of acute infection.			Died 6th day of disease.
M. C.	Female	67	Sore throat and agranu- locytosis developed in hospital	Pharynx very red and oedematous.			Died 2nd day following sore throat and first evidence of agranulocytosis.
Case of Dr. Scott	White Female	78	3 days be- fore taking history	Ulceration of tonsils.		Large anterior cervical gland enlarged and tender.	Died 36 days after onset of disease.

and a third died three days after coming to the hospital and one day after the only transfusion. All the other three who did not receive transfusion died.

It seems well worth careful consideration, from the results of the cases I have reported here, and from favorable reports of other writers in treating the disease, to regard transfusions given only a few days apart and at the earliest available moment of the disease, as one of the most valuable adjuncts in the treatment of agranulocytic angina.

SUMMARY

It seems reasonable to accept agranulocytic angina as a definite clinical picture.

No etiological factor has been proven as the causative agent in the disease, and there is some doubt whether sepsis, or the loss of power of the bone marrow to form granulocytes, is the primary lesion. Many different types of bacteria have been found in the blood stream as well as the local lesions. Such a variety of findings does not permit of any conclusions as to a specific organism being the causative agent.

Experimental work on guinea pigs has shown that B pyocyaneus has some effect upon the granulocytes both in reducing the number and in having a toxic effect on the cells.

Sepsis undoubtedly plays a role. With recur-

rent agranulocytosis it would seem the bone marrow of some individuals is very sensitive. A reasonable explanation, and one most likely, is that an overwhelming protein reaction on the bone marrow of a sensitive individual takes place, or that a sensitive granulocytic system is affected by the noxious agent of a septic process.

It is unlikely the tonsils are the necessary portals of entry, when ulcerations appear in other parts of the body. In some cases ulcerations have occurred without affecting the tonsils, or the tonsils have been a later manifestation, 12 days following foreign protein injection.

The great majority of cases occur in women past middle life, but occur in both sexes and is not limited to any age.

It is characterized by ulcerations, which are most frequently in the mouth, pharynx, and buccal membranes, and which have occurred not infrequently in the skin, vagina, and anus and have been described in the stomach.

The disease, if fatal, is usually short. Jaundice is seen not infrequently. It is generally accepted to be without hemorrhagic diathesis although a number of cases show a secondary anaemia. Anaemia is not an outstanding feature. In some cases, the erythrocytes have been increased. The platelet count is usually normal. The reduction of leukocytes and granulocytes is the outstanding

TABLE OF SIX NEW CASES REPORTED—Continued from page 6

Name	Temp	Complications	Anaemia	Throat Culture	Blood Culture	Treatment
B S	104 to 105	Pneumonia	Slight	Staphylococcus long and short chain streptococci		Tracheotomy. Local to mouth. Day before death blood transfusion 500 c c Linderman method
I N R	To 103½	Cellulitis of ear Suppuration left Submaxillary gland			Staphylococcus hemolyticus	4 transfusions 500 c c each Linderman method Incision and drainage left submaxillary Soda cacodylate 3 days after third transfusion
A J	To 104	Bronchio pneumonia, abscess over sacrum	Moderate anaemia		Vincent's organisms on four examinations	Abscess opened and drained Liver extract 2 blood transfusions Alpine light treatment
L M	To 105	Acute dachryocystitis				
M C	To 106				Streptococcus hemolyticus	Local throat treatment

feature. The extremely low leukocyte count, along with the absence, or almost absence, of granulocytes, the absence of haemorrhagic diathesis, the slight change, if any, in the number of erythrocytes and platelets, the ulceronecrotic lesions, a severe infectious condition, the predominance in females, sometimes an icterus, are the important factors in making a differential diagnosis.

Recurrent agranulocytosis with angina has been reported by a number of authors. The pathological reports are variable. Bacterial emboli with ulcerations, resulting from the occluded blood vessels, are significant findings. Frequently, changes of the viscera have been seen which go with a septic condition. The most persistent finding has been an alteration in the bone marrow, with almost complete disappearance of the granular leukocytes.

Pneumonia, abscesses and suppurations of the lymph and salivary glands are the most frequent complications noted.

The mortality is high, but it can no longer be considered a hopeless disease. Cases have been reported as recovered without any specific therapy. From past and recent reports of irradiation of the long bones, it would seem this form of treatment deserves careful consideration when it is in the hands of an experienced roentgenotherapist. Transfusions have been sufficiently tried to give favorable comment, when they are given at the earliest available moment of the disease, at only two or three day intervals.

THE EFFECT OF X-RAY ON THE WHITE BLOOD CELLS

By WILLIAM H. STEWART, M.D., and H. EARL ILLICK, M.D., NEW YORK, N. Y.

THE effect on the white cells of the blood is directly dependent on such factors as the quantity of X-Ray and the length of time administered; the size of the surface area (portal) of the body through which the rays pass; the region or organs of the body which are exposed and the frequency of repetition of the exposure.

In brief, the effect of the X-Ray on the leukocytes depends on the dosage. The greater the quantity, the more frequent the application of the rays and the larger the portal, the more profound the reaction. There may be a daily exposure of the entire body as a doctor while fluoroscoping and only a slight amount of X-Ray be absorbed if the machine is manipulated properly. Years of experience teaches that there is no perceptible change in the leukocytes IF certain rules of protection are followed. Too often fluoroscopic machines are installed with no other thought than its possible helpfulness in diagnosis. No one warns the doctor that it is a lethal machine using high voltages which may harm the user or patient unless certain precautions are observed. Patients as well as doctors have been accidentally killed and many more have been injured by fluoroscopes utilized without proper working knowledge. An absolute requisite is a built-in filter between the tube and the patient. Lead glass in front of the fluoroscopic screen is also essential to protect the doctor. The fluoroscopic diaphragm should be kept closed as far as permissible while the machine is in use in order to properly observe the region being examined so that as small a portal of entry of X-Ray into the body of the patient be employed as practicable. It is highly important to wait in a darkened room until the pupils are entirely accommodated before starting to use a fluoroscope in order to lessen the amount of X-Ray employed and to obtain a clearer image. Acquiring complete accommodation is often the real reason why one fluoroscope seems superior to another when in truth the machines are equally efficient. Failure to comply with this essential means that the examiner in order to obtain clear screen visualization immediately, uses much more current than he should and risks harming the patient and himself by a prolonged exposure. Lead gloves should always be used even if only infrequent examinations are made. A lead apron is also indispensable, its objectionable weight being overcome by hanging it over the back of a chair and then straddling the chair with the apron in front of the examiner's body. It is only infrequently that fluoroscopy alone is persisted in to such an extent that actual changes occur in the white blood cells. One doing fluoroscopy for prolonged intervals should have frequent blood counts taken. He should

also try Pfahler's test (1) by carrying around in his pocket a dental film facing outwards for two weeks; if upon development there is any fogging or blackening of the film he should improve his protective appliances as his present are inadequate. Oil-immersed fluoroscopic units are ideal because they are shock-proof and afford maximum protection. Danger of explosion when anaesthesia is being used during fracture reduction is also minimized. In such installations an oil-immersed foot-switch is also requisite.

The roentgenologist or worker constantly exposed to X-Ray needs additional protection such as a lead-lined control booth which is located as far as possible from the tube being energized. A lead-glass bowl or tube with auto-protective covering is a necessity to prevent undue exposure. The new high-milliamperage outfits particularly need these protective devices for the operator. A periodic blood count preferably monthly is advisable and in institutions with proper protection where this has been done only slight changes have been found in the counts limited usually to a higher proportion of lymphocytes and sometimes a leukopenia. A. E. Barclay of Cambridge Medical Schools (2) as well as other investigators have found that when the usual protective devices are used the amount of X-Ray absorbed by the technician is practically negligible and does not seriously affect the blood count. Dr. Barclay aptly compares the known slight effect on the blood count in cancer cases where there is prolonged X-Ray treatment consisting of massive doses frequently repeated over some years time with the small daily doses which the average technician receives. It is Dr. Barclay's opinion that proper ventilation is the most important preventive factor in combating the effects of the X-Rays upon the blood cells.

Senn (3) in 1903 was the first to observe and report the reaction of the leukocyte count in leukemia following X-Ray exposure.

Heineke (4) in 1904 from animal experiments first demonstrated a decrease in the lymphocytes in the circulating blood and destruction of lymphoid tissue in the spleen and lymph glands. He found that white cells were decreased after large doses of X-Ray and that the polymorphonuclear cells were proportionately increased. After several days the lymphocytes disappeared almost entirely. The normal proportion was regained later if no more X-Ray were administered.

Roentgen therapy usually decreases the number of white blood cells especially the lymphocytes and increases the relative number of polymorphonuclear neutrophils. A leukopenia may ensue after repeated irradiation. Very small doses act as a stimulus to the lymphforming organs and

cause a lymphocytosis. The lymphocyte is regarded as the most radiosensitive cell in the blood. Levin (5) explains the mechanism of the action of the rays on the leukocytes as a "destruction of the lymphocytes which is then followed by the release of the polymorphonuclear leukocytes from the bone marrow or by an overproduction of this type of cells by the blood-forming organs."

MacKee (6) notes that "after intensive irradiation, hyperplastic changes have been observed in the bone marrow, while the spleen and lymphatic glands show atrophy and reduction in size." Warthin (7) demonstrated that the X-Rays had the same effect on bone marrow as on the circulating lymphocytes but to less degree.

Isaacs (8) believes that "the quickest response in reduction of the white blood cell count after adequate therapy comes when the bulk of the cells are small and medium-sized (i.e. relatively mature) lymphocytes, and the response is but slight when the bulk of the cells are large lymphocytes and lymphoblasts (young cells)." The explanation is that "exposure to roentgen irradiation during the primitive lymphoblast and lymphoblast stages, causes the cells to reproduce with the rapid production of additional primitive lymphoblasts. As the bulk of the cells are in this stage in acute lymphatic leukemia and the terminal stage of chronic lymphatic leukemia, roentgen irradiation does not lower the white blood cell count appreciably. When the bulk of the cells are medium or small-sized lymphocytes, roentgen irradiation stimulates them to grow old and the count is lowered."

Minot and Spurling (9) find that the "most important effect of the customary therapeutic doses of irradiation is to decrease the number of white blood cells especially lymphocytes so that leukopenia may occur." If the white cells fall below 3000, however, treatment is usually not advisable with the exception of cases of agranulocytosis in which the granular white cells are very few in number or missing entirely in the blood stream. Thomas, Taylor, and Witherbee (10) from animal experiments found that polymorphonuclear cells were increased in number for a short time after X-Ray application. Friedeman in 1927 (11) reported improvement in cases of marked leukopenia after irradiation of the bone marrow by X-Ray. Waters and Firor (12) have also been successful in combating agranulocytosis with roentgen therapy.

Therapeutic doses of X-Ray in the treatment of blood cell disorders are employed with benefit mainly in the leukemias, lymphomata, lymphosarcoma, Hodgkins, polycythemia and recently in agranulocytosis. Anemia whether primary or secondary is usually considered a contraindication especially if advanced changes are present.

SUMMARY

1. Protective devices are an absolute necessity in every fluoroscope; also for radiography and treatment.

2. Periodic blood counts should be taken on every roentgen worker and patient receiving X-Ray therapy. A leukopenia or increased proportion of lymphocytes or an anemia is indication that inadequate protection is in use.

3. Irradiation is beneficial in certain blood dyscrasias either by reducing the number of lymphocytes or stimulating formation of granular cells.

THE DIAGNOSIS OF CORONARY OCCLUSION*

By ALFRED M. WEDD, M.D., CLIFTON SPRINGS, N. Y.

OWING to the many communications that have appeared in recent years on various phases of the subject, knowledge of coronary occlusion as clinical entity has become widely diffused. It seems quite certain that there has been an increase in the incidence of this lesion in all western countries, far greater than may be accounted for by enhanced diagnostic acumen. Coronary occlusion is now known to be one of the most common causes of sudden death and comprises most of the fatal cases diagnosed as acute indigestion or acute dilation of the heart. The diagnosis of coronary occlusion is made so readily by physicians and surgeons that the question may now be raised, whether or not the problem has become too simple and the diagnosis made too frequently. For that reason it has seemed advisable at this time to review the diagnostic criteria and to consider differential diagnosis.

The typical picture of acute occlusion of a large vessel, which includes severe pain, shock, fever, leucocytosis, and myocardial failure is now familiar to most practitioners. The symptoms of coronary occlusion may be apportioned to three inter-related sources; the occlusion itself, the subsequent infarction of the myocardium, and involvement of the nervous system. Pain, localized tenderness, hyperesthesia, and certain disorders of the cardiac rhythm are due to disturbances in nervous pathways. As to the mechanism of pain production, many words have been used, such as vascular spasm, vessel distention, arteritis, aortitis, muscle cramp, ischemia, anoxemia, acid metabolites, but a wholly satisfactory explanation has yet to be given. This criticism is based on the simple fact that there are many more examples of advanced coronary sclerosis, aortic disease, coronary occlusion, and myocardial insufficiency than there are of cardiac pain. The mechanism is probably not the same in all types of heart disease. The actual vascular occlusion is responsible for the state of shock which occurs early, with fall in blood pressure, dyspnea, and perhaps the early signs of heart failure. Infarction in the myocardium is responsible for fever, leucocytosis, pericardial friction rub, changes in the electrocardiogram, the later appearance of congestive heart failure, embolic phenomena, and certain alterations in rhythm, e.g., heart block when the artery to the A-V node has been obliterated. From the clinical standpoint coronary occlusion may be divided into two main groups, as was done by von Leyden many years ago, those whose onset is accompanied by severe pain, and those which begin

with acute heart weakness and in which dyspnea is the outstanding symptom.

Pain which has its origin in the heart or aorta is for the most part referred to those areas which are supplied by the eighth cervical to the seventh dorsal nerves, inclusive. There are also connections with the vagus, and in some instances with sensory branches of the fifth cranial nerve. The most frequent site of pain is substernal, especially beneath the upper sternum. Epigastric pain is not uncommon. Radiation occurs to the shoulders, the arms, more commonly the left and most often the inner aspect, the neck, face, lower jaw, and rarely the mastoid area. The character of the pain is subject to wide variation. It may be of a burning or gnawing type, called "heart burn" and attributed to indigestion. It may be short and stabbing, or gripping and vise-like in character, with a sense of intense thoracic constriction. Neither the character of the pain nor its severity are constantly related to the size of the coronary vessel involved or to the extent of the lesion produced.

Relatively less frequent but actually quite numerous are those cases of coronary occlusion in which pain is entirely absent, or insignificant, and severe dyspnea is the dominant symptom. These cases are usually diagnosed asthma, or cardiac asthma and the underlying pathology is not appreciated. When an attack of severe dyspnea occurs suddenly in a patient past 45 years of age who has not been subject to attacks of bronchial asthma, and when there are no reasons for suspecting pulmonary embolism, coronary occlusion should be considered. The following example illustrates non-anginal occlusion:

The patient was a man 56 years of age. For several years he frequently had epigastric pain which came on about one hour after meals and which was usually relieved by bicarbonate of soda. For one year prior to his final illness he was subject to dyspnea on exertion. On the evening of May 20th, 1930, he was taking his family for a motor drive when an attack of severe dyspnea came on suddenly. He got out of the car and for some minutes sat on the running board panting for breath. Finally he was able to drive his car home. When he returned, he took soda, expelled a large amount of gas, and fell momentarily unconscious. There was no pain associated with this attack. The subsequent course was one of progressive congestive heart failure from which he died on September 21st, 1930. Examination of the heart showed an occlusion of the main left coronary artery about 2 cm. from the mouth, which had resulted in extensive infarction in the left ventricle. There were large patches of replacement fibrosis. A

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 3, 1931.

thrombus was present in the apex of the cavity. The circumflex branch was also entirely occluded. In the pyloric ring of the stomach were two areas of ulceration with hard indurated walls; the base of one of these was adherent to the pancreas. These ulcers explained the digestive distress from which the patient had long suffered.

Pain may occur in any form of heart disease and all possible types will be described by patients. In the present discussion, the problem will be limited to the differentiation of pain associated with coronary thrombosis from that related to simple anginal attacks, a problem which has been created largely by the loose usage of the term *angina pectoris*. Herberden coined this term for those who suffered from breast pang which occurred on exertion—"while they are walking, more especially if it be up hill or shortly after eating." *Angina pectoris* should be limited to those painful seizures which are produced by effort, emotion, food, or cold. If that be done, the problem then narrows itself to the differentiation of occlusion of small or of large vessels. When pain is related to occlusion of a vessel, it is usually of longer duration, and is more difficult to relieve; rest or nitrites, which terminate simple anginal attacks, are insufficient. One or several doses of opium may be required. Individual sensitivity to pain must be taken into consideration. Long continued severe pain, or a series of frequent pains occurring at rest or on slight provocation and which continue for several days—the *status anginosus*—is diagnostic of coronary occlusion. The later symptoms that result from infarction have already been mentioned. When a small vessel is involved, signs of myocardial insufficiency probably will not appear. The electrocardiograph may render important service in differential diagnosis. Changes in the electrocardiogram during attacks of simple angina, as far as is now known, do not occur or are limited for the most part to changes in the direction of the

"T" waves. Following the occlusion of a vessel of any considerable size, there is a characteristic alteration in the ventricular complexes of the electrocardiogram which has been described by Pardee and others. In typical examples, there is a fusion of the "R" and "T" waves in which "T" takes off from the descending limb of "R" before that wave has returned to the base line (Figure 1). The change in the ventricular complex is dependent, at least in part, on the extent

FIGURE 1

Electrocardiogram with ventricular complexes characteristic of coronary occlusion.

of the muscle involved and so variations from the typical occlusion complex are to be expected. There is also a time factor to be considered, for these characteristic changes may not appear until twelve or more hours after the onset of the attack (Figure 2). A syndrome called "*angina decubitus*" to describe painful seizures which occur at rest has been stressed by French clinicians. That it is a distinct form of "*angina*" may be doubted. Such attacks are probably either simple

FIGURE 2

A. Normal electrocardiogram, before coronary occlusion.

B. Three hours after onset of pain.

C. Twenty-four hours after onset.

anginal attacks for which the exciting cause is not apparent, or they represent occlusion of small vessels. However, there will doubtless occur many painful seizures in which the differentiation between a simple anginal attack of the effort type and an occlusion of a small vessel will be impossible.

The sudden replacement of a normal cardiac rhythm by auricular fibrillation may be followed by a state of partial collapse, fall in blood pressure, rapid engorgement of the liver, and epigastric pain. This clinical picture has been mistaken for some acute abdominal trouble. In a recent case of hypertensive heart disease it was found impossible to decide whether the same sequence of events resulted from thrombosis of one of the branches of the right coronary artery, or whether all the symptoms were due to the onset of auricular fibrillation. In this instance the fibrillation lasted for less than forty-eight hours. Electrocardiograms taken a few hours after the attack and during the subsequent weeks showed ventricular complexes that were similar in all detail to those recorded before the attack, nor was there any later clinical evidence which pointed to thrombosis. The leucocyte count rose to 28,600 three hours after the attack; neutrophils constituted 80 per cent of the white cells, and eosinophiles and basophiles, which were not reported on admission, were present. It may be noted in passing that leucocytosis is probably a constant accompaniment of vascular accidents. The maximum number of white cells varies widely, but in proved cases a high percentage of neutrophils and the absence of eosinophiles has constantly been observed. The various factors responsible for leucocytosis are not clearly understood, but that this white blood picture is not characteristic of infection is now certain. The rôle of the sympathetic nervous system is probably an important one. A second example in which the onset of auricular fibrillation was associated with symptoms similar to coronary occlusion may also be given. A young woman, 27 years of age, who was known to have had mitral stenosis for many years, experienced severe twisting pain in the arms and later chest soreness, simultaneously with the onset of auricular fibrillation. She stated that the attack did not "knock her out" and she continued up and about for an hour or more when her physician arrived. He made a diagnosis of coronary occlusion and ordered her to bed. The subsequent clinical course has brought forth no evidence of such an accident. Levine⁴ has frequently encountered auricular fibrillation after coronary occlusion, but in my own experience it has been rarely observed. In the two examples cited there is no proof of absence of occlusion. The failure of the electrocardiogram to show changes in the first case does not exclude occlusion. Occlusion does seem unlikely in the second case; the pain was doubtless

of cardiac origin, but not necessarily caused by occlusion of a vessel. Because of the profound disturbance that may follow the onset of auricular fibrillation it is not unreasonable to consider that at times the picture may imitate coronary occlusion.

There are a number of other vascular accidents which at the time of onset may simulate coronary thrombosis. Rupture of the aorta may be mentioned; this accident, also, may occasionally occur without pain. In two instances supposed coronary thrombosis was found to be thrombosis of the pulmonary artery. However, both of these conditions are promptly fatal and the differentiation is not practical. Occlusion of a mesenteric vessel, particularly when it occurs in a patient who has heart disease, may suggest coronary thrombosis, but this will soon be followed by signs of peritoneal irritation, which never appear after coronary occlusion. Occlusion of a splenic vessel, such as commonly occurs in subacute bacterial endocarditis, may suggest coronary occlusion, but usually the pain is definitely localized in the left side of the abdomen. Likewise, occlusion of a renal artery by a mural thrombus has raised the question of a coronary occlusion. The later course of these accidents makes their nature clear.

Of great importance is the differentiation of substernal pain which is of cardiac or aortic origin from that which arises in some viscus of the alimentary system. The problem results from the fact that not only disturbances originating in the esophagus but in any part of the alimentary canal may reflexly give rise to pain which will be referred beneath the sternum. Moreover, there is some overlap in the spinal connections of the heart and those of certain alimentary viscera. However, the radiation of pain is usually not the same. It is the consensus of most observers that substernal or epigastric pain which has its origin in the digestive tract does not radiate into the arms. This is to be expected, for the sensory spinal connections for the esophagus, stomach, gall bladder and small intestine are through the fifth to the tenth thoracic nerves. The direct relation of pain to effort and its radiation to the arms speaks for cardiac pain. But many occasions will arise in which the differentiation of cardiac from alimentary pain will be at the same time difficult and important, and in this connection it should be borne in mind that coronary occlusion by no means always occurs as an acute accident. In the following case substernal distress was erroneously attributed to indigestion. The history also illustrates the mildness of symptoms in certain cases of coronary occlusion.

Mr. T. K. had been perfectly well since an appendectomy was performed when he was twenty-two years of age. At the age of forty-four years, he began to suffer from a burning sensation beneath the sternum. This was often

accompanied by sweating of the head and face. At that time he had unusual business worries and had become nervous. The substernal distress was attributed to nervous indigestion, and it subsided after about three months during which symptomatic treatment was given. The heart was said to be normal at that time, although a thorough examination had not been made. There were no definite cardiac symptoms and the man was not incapacitated. Some months later he began to experience palpitation on exertion and still later, dyspnea. He died at the age of forty-six from an easily recognizable coronary occlusion. From the examination of the heart it seemed quite certain that the period of nervous indigestion corresponded with occlusion of the main left coronary artery which had later become canalized, but which had resulted in extensive fibrosis of the wall of the left ventricle. There was also an old occlusion of the descending portion of the left coronary artery. The final event, which occurred two weeks before death, caused infarction of the interventricular septum and the formation of a mural thrombus.

There are both functional disturbances and organic diseases in the esophagus which may give rise to substernal pain. The severity of the pain when it first appears will usually lack the intensity of the pain of coronary thrombosis. Pain caused by carcinoma of the esophagus is related to swallowing movements, at least early in the disease, and regurgitation of food or saliva is apt to occur. Examination of the esophagus with a barium bolus will be helpful. Esophageal pouches are usually painless. It is conceivable that a cardiospasm may suggest coronary thrombosis. However, according to Walton,² cardiospasm is usually insidious at the onset and presents a long history. The pain at first is intermittent, and follows the ingestion of each mouthful of food. When the esophagus becomes distended there may be dyspnea, together with a stifling sensation, and at such times confusion with cardiac pain may arise. By this time characteristic vomiting is usually present. Likewise, spasm of the pylorus may simulate coronary occlusion.

This problem presented itself once in the case of a highly nervous woman of nearly sixty years of age. She had taken no breakfast and later in the morning, following a bath, ate a pear. After fifteen minutes she began to have severe epigastric pain, much flatulence, and later abdominal distention. The blood pressure at first rose considerably above the patient's normal, and then fell below normal. Heat was helpful in relieving the pain, but pantopon and atropine were finally necessary. The following day a second attack occurred; abdominal distention was not marked and it was possible to palpate a tender mass in the epigastrium which was believed to be the pylorus. There was neither fever nor leucocytosis, and no subsequent changes in the electrocardiogram.

One week later a calcified thyroid tumor was removed and the patient made an uneventful recovery. The severe painful seizures were attributed to pylorospasm.

Inasmuch as coronary thrombosis may be accompanied by nausea and vomiting as well as severe epigastric pain, there are occasions when the differentiation between this lesion and some acute surgical condition of the abdomen will be of utmost importance. At the onset, coronary occlusion, rupture of gastric or duodenal ulcer, acute intestinal obstruction, or acute pancreatitis may present a similar clinical picture. Epigastric tenderness and rectus rigidity usually are not present following coronary thrombosis, and when they do occur these symptoms are comparatively mild. To differentiate a cardiac accident from an "acute abdomen," one must consider on the one hand the radiation of the pain, the absence of rigidity and the appearance of signs of myocardial failure; and on the other hand, early rigidity, followed by other signs of peritoneal involvement. The electrocardiogram may be of great value in such cases and should be obtained before laparotomy is performed. The early differentiation between coronary occlusion and acute pancreatitis does not seem possible. Two examples will illustrate the foregoing points.

A hardworking farmer, 38 years of age, who had never had any serious illness and was thought to be in perfect health was seized with acute pain beneath the lower end of the sternum while sawing wood. Breathing became difficult because of increased pain. Partly by walking and partly by riding he was able to return to his home. When he reached there he was perspiring profusely and was nauseated. After taking soda he vomited a little food and mucus. The pain was not referred to the back or to the arms. He arrived at the hospital eight hours later. A preliminary diagnosis of ruptured gastric ulcer was made, and he was admitted to the surgical service. Morphine was necessary to relieve the pain. The leucocyte count on admission was 16,400, with 86.7 per cent neutrophils and 13.3 per cent lymphocytes. Fever was only slight. Nine hours after the onset of the severe pain the physical examination of the abdomen was practically negative. The electrocardiogram was highly abnormal (Figure 3). The diagnosis was then revised to coronary occlusion. Eleven weeks later the patient died suddenly. An examination of the heart revealed a plaque and fibrinous material obstructing the left main coronary artery, two areas of softening in the left ventricle and a large mural thrombus on its inner wall.

An elderly man who was under observation in the hospital because of an advanced carcinoma of the bladder was suddenly seized with severe upper abdominal pain and went into a state of partial shock. Previous examination of his heart had shown nothing of significance. The history

of digestive disturbances had not been impressive, and because of his age and the mode of onset of the attack, coronary thrombosis was considered. Within one hour the abdomen became tender and rigid and, although his condition became rapidly worse, no signs of cardiac failure developed, so that it was believed that the trouble arose in the abdomen. Death occurred within

The patient, a man 58 years of age, was known to have suffered from hypertensive heart disease for some years. He was admitted to the hospital two days after the onset of an attack of abdominal pain. There were some signs of congestive failure; the blood pressure had fallen, auricular fibrillation was present, and the ventricular complexes in the third lead of the electrocardiogram suggested the possibility of coronary occlusion. Because of the condition of the heart and the fact that the abdominal symptoms had been varying, it was decided to delay operation until the following morning. By that time the heart had definitely improved, but the abdominal signs had progressed and tenderness and rigidity were definitely localized in the right lower quadrant, so that a diagnosis of appendiceal abscess was certain. The patient died from general peritonitis. The coronary arteries were patent, and save for an area of fibrosis which included the base of the papillary muscle in the right ventricle, the condition of the myocardium was good.

SUMMARY

Substernal or epigastric pain which arises in the heart or aorta is related to effort, and radiates into the shoulders and arms, in contradistinction to pain referred to the same sites but which originates in other thoracic or in alimentary viscera. Pain due to coronary occlusion is usually more severe, of longer duration, and more difficult to relieve than cardiac pain not associated with obliteration of a vessel; the so-called status anginosus is characteristic of occlusion. The subsequent appearance of fever, leucocytosis, pericardial friction rub and signs of myocardial insufficiency is evidence of cardiac infarction, secondary to occlusion.

When the onset of auricular fibrillation is accompanied by pain, the clinical picture may suggest coronary occlusion.

Certain other vascular accidents, rupture of the aorta, pulmonary thrombosis or embolism, or occlusion of certain abdominal vessels may simulate coronary occlusion.

The differentiation of coronary occlusion from one of those lesions comprised by the term "acute abdomen" may at times be necessary. The former is characterized by radiation of pain to the arms, absence of abdominal rigidity, and signs of cardiac failure; the latter group, by early rigidity and signs of peritoneal involvement.

The electrocardiogram may be of great help in differentiating pain associated with occlusion of a vessel from other types of cardiac pain of less moment. It may also be of value in the differentiation of cardiac from abdominal lesions by indicating myocardial disease.

Coronary occlusion frequently occurs without pain, but with severe dyspnea as the dominant symptom. The true nature of these cases should

FIGURE 3

Electrocardiogram from a case of coronary occlusion which simulated a ruptured gastric ulcer.

four hours and when the abdomen was opened a perforated duodenal ulcer was found.

Coronary occlusion may at times resemble cholelithiasis, but Faulkner, Marble, and White³ who have investigated this phase of the problem considered that usually it did not. Coronary disease is more common in men, while gall stones are more frequent in women. In gall stone colic the pain is usually referred to the back and beneath the right shoulder, and this pain is followed by muscle tenderness and rigidity in the region of the gall bladder. Here again, pain is not referred to the arms. Except when rupture of the gall bladder occurs, immediate surgical intervention is not required, and there is time to establish a diagnosis.

There is ordinarily little likelihood that coronary occlusion and acute appendicitis may be confused, but when the latter appears in a patient in whom one might anticipate coronary occlusion the question of differentiation may arise. The recognition of abdominal complications in cardiac patients must always be more difficult than when they occur in normal individuals. In a recent patient this difficulty was encountered.

be recognized; they should not be dismissed with a diagnosis of "asthma."

A STUDY OF THE RESULTS OBTAINED BY THE USE OF ARTIFICIAL ULTRAVIOLET RADIATION IN TWO HUNDRED NON-TUBERCULOUS CASES

By SAMUEL I. MULLER, M.D., LONG ISLAND CITY, N. Y.

FOR the purpose of this study we have gathered two hundred cases. The age began with an infant at nine months and extended to a limit of 65 years in the adult. The large majority came between the age limits of 15 to 30 years. The sex was almost evenly divided. By occupation, the large majority was non-laboring. The social status was almost equally divided between single and married individuals, in moderate to comfortable circumstances. Nationality played no part in this series. The conditions treated were divided into the following three classifications: 1. *Nutritional*. 2. *Infectious*. 3. *Nervous*. These made up 30 per cent, 65 per cent and 5 per cent of our series respectively. The classification was made on the most prominent underlying condition to be treated by radiation. The series was further divide into individuals who received artificial ultraviolet radiation and those who were advised a change of environment at seashore or mountains, with rest, diet, proper regimen and medication. A comparative study of results of both methods was then made in like cases.

Since we are primarily interested in a study of results of this application, the principles of its action, technique and contraindications are passed over, as elementary and very thoroughly considered in available texts. Concerning its application, however, the following points are of value. A very thorough study of the individual is made preliminary to any treatment. The necessary regimen of living, diet, rest, activities, etc., is instituted together with whatever medical or surgical treatment may be indicated, prior to or during the course of radiation. No radiation is undertaken, where a sufficient time is not available, a minimum of two months, to exhibit results from its use. The preliminary study of the individual may include laboratory and x-ray examinations, where indicated by the condition under consideration. We consider treatment by this modality successful, when we have achieved the following results: 1. A destruction of infection and its demonstrable changes within the tissues. 2. General nutritional effects, as better absorption

and utilization of foods, with an increase of weight and invigoration of the body. 3. When general complaints of fatigue and depression are overcome and replaced by a feeling of well-being and we have an individual, able and willing to resume his or her usual occupation and social activities. Clinical studies will serve to illustrate the three classifications of conditions treated.

Nutritional: Baby C. was first seen at the age of nine months. She was treated for bronchitis, clearing up in five days. During general examination, weight was noted, nine pounds, two ounces. She was five pounds 8 ounces at birth. Breast fed for two months and bottle formula fed by direction of a prominent pediatricist to nine months. The child would not thrive and at the time was taking only four ounces feeding with difficulty. At baby's first visit, history disclosed regurgitation of curd. Formula was modified to overcome this. Ultraviolet radiation was begun and given three times weekly. It is to be noted that when the baby was given viosterol by the pediatricist, she would take no feeding at all. In less than three weeks the baby had gained 13 ounces. At six weeks the baby was taking seven ounces to a feeding. At 9 weeks the baby had gained one pound, ten ounces and had cut six incisors, where before radiation there were no teeth. Where baby was gaining an average of 1.3 ounces weekly since birth to the time of this study, she gained 4.3 ounces for the first three weeks and then dentition cut the average down to 2.9 ounces for the balance of the two months period. At this time excessive heat of the summer affected the baby, it began to lose weight, the mother had previously stopped radiation of her own accord and for better nursing care hospitalization was advised. With cool days baby immediately resumed feeding, but our study was discontinued. We note further that from an apathetic, fretful baby, we developed a cheerful, lively baby which began to take formula feedings and cereal gruels in a manner hitherto thought impossible.

Infectious: Mr. M., age 35, married, white, firemen, 170 pounds, was treated for grippe, until another physician disclosed a right otitis media

and mastoiditis. He had a very hectic post-operative course being treated for a suspected meningitis and later developing fluctuation in the right iliac region, which upon incision drained for two months. He received three transfusions of blood. On discharge from the hospital his weight was 108 pounds. He was advised a convalescence in the country, from which he shortly returned because of no improvement, no gain in either weight or strength. He came to the writer, was placed on proper diet, hematinic medication and given artificial ultraviolet radiation. In one month he had gained 18 pounds and at the end of six months he was 208 pounds, without evidence of infection, absorption of toxins or residual complaint.

Nervous. This classification is further divided into 1 *Local* 2 *General Local*. Mrs. W., age 64, widow, houseworker, complained of very severe pain over the right side of forehead, face and neck. Examination disclosed a herpes zoster. She had received local treatment and narcotic for pain without relief, having spent three sleepless nights. One exposure to ultraviolet radiation gave immediate relief of severe pain and two more cleared the condition up entirely, without any medication. **General.** Mrs. H., age 21, married, school teacher, had lost 14 pounds and came to the writer with a diagnosis of pulmonary tuberculosis. X-ray and sputum examination proved negative. A careful history elicited the fact that she suffered from dyspareunia and that her complaints began with this factor and her marriage, finally involving her nutrition and causing a neurasthenia. Appropriate advice was given to correct the dyspareunia and the neurasthenia was treated by exposure to ultraviolet radiation. She gained seven pounds in six weeks and began to look on life more cheerfully. The dyspareunia abated with the measures resorted to. During the course of radiation Mrs. H. stopped for an interval of one week going to Atlantic City. While there she rested, ate according to her own description "ravenously." On her return she had lost two pounds. 2 Another case which came in without any physical complaint but with a set of conditions which arose following a physical examination for life insurance, is the following. Mr. H., age 41, married, interior decorator, weight 144 pounds, rejected by an insurance company on his application. He had lost ten pounds since and presented a very definite neurasthenia. Cause of rejection was a very mild mitral stenosis with complete compensation and function. He was reassured concerning his heart condition and received ultraviolet radiation. His symptoms disappeared and he gained 22 pounds.

While the study of the above results as case records, is interesting, a proportion of the 200 cases have been studied from a different angle. Comparison has been made between the results of ultraviolet radiation, with proper regimen diet,

medication and change of climate, environment or vacation, with regulation of activities, diet and medication. *Examples follow.* Mr. B., age 30, single, an accountant, weight 115 pounds, 25 pounds underweight for years, had taken positions out of the city and annual vacations, in an effort to overcome this deficiency, otherwise in good health and without complaint. He had given up all idea of increasing his weight. The condition was brought to attention again by recovery from a bronchitis. Artificial ultraviolet radiation was started. Within two months he had gained 15 pounds, while retaining his position in the city. He continued his usual diet, activities and mode of living and after radiation had stopped gained another 25 pounds. This gain has remained and the increase is permanent. 2 Mr. L., age 24, single, mechanic, normal in weight, but complaining of a tired, easily exhausted feeling, with a family history of pulmonary tuberculosis left this city to live with a sister in rural New Jersey, to overcome any pre-disposition inherited from his family and received other medical supervision, to further aid the condition. He felt well while not working and resumed lighter work. His improvement continued until he resumed his usual occupation, when all his previous complaints returned. He came for the treatment of a relative and in a discouraged way brought up his own complaints. He was exposed to artificial ultraviolet radiation. After two months he left New Jersey to return to this city, resumed his usual occupation and had gained 15 pounds. He does no longer complain. Prior to each winter season he voluntarily presents himself for a course of radiation lasting one month, to maintain his physical condition. 3 Mr. A., age 21 years, single, broker's clerk, lives in the country, had a prolonged convalescence from broncho pneumonia following grippé infection. He did absolutely no work for a year, had the benefit of all the best milk and eggs, cared for, climate, rest, sunshine, outdoor sleeping porch and other advantages calculated to completely restore his health, besides medication. When well his top weight was 155 pounds. Following pneumonia his weight was 121 pounds, that is, after three months. He was unable to leave his bed before two months. His improvement did not advance over the stage of loss of cough, increase in weight, five pounds and increased red cell count. He was unable to shake off fatigue, irritability and restlessness, in spite of all his advantages and after a constitutional benefit to himself of residence in the country for ten years prior to his pneumonia. His improvement remained stationary. X-ray examination of his chest was negative. He was exposed to ultraviolet radiation and after two weeks was able to come to the office himself. After three months his weight was 172 pounds. He was able to resume such activities as tennis, swimming, driving

and working in his father's manufacturing plant. Every year prior to winter season he receives a course of two month's exposure to ultraviolet radiation and has maintained his condition without even a cold for three years.

Comparison of Results: Climate, environment and vacation involving changes in humidity, altitude and air cause improvement in 50 per cent. Radiation involving the use of ultraviolet light alone improves 90 per cent. In both, best results are secured when proper regulation of activities, diet and habits of living are added. Medication further aids the benefits from either. In a study of the 50 per cent benefited by climate, etc., ten per cent of these are benefited directly by climate, etc., while the balance or forty per cent attribute their improvement to these factors plus especially, proper regulation of activities, diet and habits of living, to which they are not amenable or are unable to achieve at home. With radiation this is not a prominent factor since these individuals are at home. Seventy per cent of those receiving radiation follow their usual occupations. As against this change of climate, etc., involves cessation of occupation and disruption of family life in nearly all cases. Change of climate, etc., is particularly adapted to the treatment of those who are easily quieted by unfamiliar surroundings and environment. Ultraviolet radiation is particularly adapted to individuals who desire to retain their usual occupation and mode of living and yet receive medical care. The mental attitude of the individual sometimes indicates the choice of methods.

Our greatest personal satisfaction with results from the use of this modality lies in the field of preventive medicine, in addition to curative and actual treatment. As an example, *Preventive:* Mrs. E., age 22, four months postpartum, came in with a diagnosis of pulmonary tuberculosis. She had a normal delivery, but her history disclosed the fact that she had not ceased to have a uterine discharge, at times blood tinged, since delivery. Digital pelvic examination showed a soft, enlarged uterus, congested adnexa and tenderness over the entire pelvis. X-ray examination of the chest showed marked thickening of the stroma, the glands of the lung and at the hila, with no evidence of infiltration of the lung by tuberculous infection. Clinical examination of the chest gave dullness over the right base with crepitant rales. Weight was 109 pounds. We have here a picture of a low grade chronic pelvic infection, infiltrating other organs of the body, non-tubercular in type. The baby was placed on a formula and bottle fed. Appropriate measures were taken for the pelvic infection, rest, diet,

medication and ultraviolet radiation given. At two months, the uterus was firm, small, normal in size, the adnexa not palpable and the pelvis not tender. The lung sounds had cleared up entirely and this woman had gained 14 pounds, normal for her height and age. Examination of the lung showed evidence of absorption of the infection. There was at no time a positive sputum or a temperature. There are others who come with the same complaints, from other causes, but it is singular that all come with the diagnosis of pulmonary tuberculosis. X-ray examination in these discloses one or more of the following conditions: thickening of the stroma or bronchial tissues, thickening or enlargement of the lymphatic glands at the hila or in the lungs, thickening or evidences of inflammation at the hila, residual evidences of pneumonia, bronchitis, dry pleurisy, etc. In some there has been a history of chronic intestinal absorption or infection, gall bladder disease, supported or unsupported by x-ray findings of irritability, bowel spasm or atony. Others have disclosed focal infection of the mouth, sinuses, pelvis of the kidney or as in Mrs. E.'s case, chronic pelvic infection. When the host shows evidences of effects on nutrition as a result of this harbored infection, when more particularly the lung becomes secondarily involved or when this infection is primarily located in the lungs and familial or personal history further causes concern, then the use of ultraviolet radiation is preventive as well as curative. We do not go into the further measures in regard to these infections, since our study concerns only ultraviolet radiations and we take for granted these measures are available in texts and fully known. Our study has further brought out the fact that many young adults, the host of infections, particularly in the chest, whose familial or personal history has been suspicious, whose nutrition has been affected so that careful men have made tentative diagnoses of pulmonary tuberculosis, without confirmation by x-ray or laboratory tests by sputum, have by appropriate measures and the use of artificial ultraviolet radiation, been restored to health and actually been saved from becoming the victims, while in lowered vitality, of pulmonary tuberculosis. This is particularly true because these individuals could not by their own personal means avail themselves of cessation of occupation, rest, proper diet, regulation of living and habits, change of climate or environment. Ultraviolet radiation here becomes a potent preventive therapeutic measure by its ability to destroy infection, create better nutrition and overcome fatigue and depression in lowered vital pre-tubercular states.

Annual meeting Hotel Statler Buffalo N.Y., May 23-25 1932

COMMITTEE ON THE HEALTH COMMISSION'S REPORT

The Joint Committee authorized by the House of Delegates on June 1, 1931, has spent several months in a study of recommendations of the Special Health Commission appointed by Governor Roosevelt on May 1, 1930, for the purpose of suggesting amendments to the public health laws especially those relating to health administration by public officials, in distinction from the practice of medicine by physicians.

Early in the year 1931, the Commission issued a preliminary report which was summarized in the Journals of January 15, 1931, page 106, and February 15, 1931, page 230, and was printed in full in the Journal of October 15, 1931, page 1208. It is important to remember that this report was "Preliminary," and that a final one has not yet been issued. However, the preliminary report contained recommendations which were

formulated into legislative bills. Some of the bills were enacted into laws during the legislative session of 1931, and others were deferred until the session of 1932.

When the House of Delegates of the Medical Society of the State of New York met on June 1, 1931, the information before it consisted of the preliminary report of the Governor's Health Commission and the legislative bills which the Governor had signed. The House, therefore, authorized the committee on Public Health and Medical Education to act jointly with the committee on Public Relations and formulate a report by the first of January, 1932. The report of that Joint Committee is printed on page 29 of this Journal, and copies have been sent to the officers of the County Societies and to the members of the House of Delegates. The report will be considered by the House of Delegates which will hold a special meeting on Thursday, January 14, 1932, in the Hotel Ten Eyck, Albany.

The feature which seems to have aroused the greatest discussion is that relating to the form of organization of local health departments. The Governor's Health Commission strongly recommends that the fundamental unit be the county, instead of the town, village, or city as at present.

The Joint Committee not only approves the general principle of a county health department, but also emphasizes the value of local home rule. It recommends the gradual adoption of the county plan as experience and natural evolution point the way. It objects to the compulsory feature of the Commission's proposal.

Physicians of New York State will be interested in the public health developments in the State of Maine, in which a Governor's Commission brought about a consolidation of about forty scattered commissions into four departments, including one on Public Health and Welfare. An account of the enactment of the law begins on page 40 of this Journal.

SCIENTIFIC EXHIBIT AT THE ANNUAL MEETING

A scientific exhibit will be an important feature of the annual meeting of the Medical Society of the State of New York to be held on May 23-25, 1932, in the Hotel Statler, Buffalo. The plans of the Chairman of the Committee on Scientific Work, Dr. Arthur J. Bedell of Albany, and his associates, will eliminate the defects of previous exhibits and will attract visitors. It is not sufficient to place specimens and charts on view,—there must be some one on hand to explain them. The Committee plans that a demonstrator shall be in constant attendance at each exhibit ready to explain the points that are to be emphasized.

The plan of demonstrators has been followed with striking success at the American Medical Association meetings. When a demonstrator was present, even at a booth of statistical charts, a number of doctors were gathered; while spectacular exhibits without demonstrators were unnoticed. The psychology of the spectators will be readily understood on an analysis of two conditions applying to a study of the exhibits.

In the first place, an exhibit is the concentrated

essence of information; and a great amount of time and thought has been given to the presentation of essentials and the elimination of unimportant features. Every part of an exhibit has an important relation to all others, and yet a visitor must grasp each part in order to comprehend the whole.

An exhibit must be labelled and charted, like a map, but it takes time and effort for a visitor to read a written description and identify the important parts. What would require five minutes to read and comprehend, a demonstrator can show in five seconds.

An exhibit is like a picture in a book, or a diagram of a machine. It is merely an illustration that affords transient pleasure, unless it is either studied or explained. A demonstrator relieves the visitor of the work and strain of deciphering the labels, and enables him to concentrate his mind on the lesson to be taught, rather than on the labor of acquiring the knowledge. Moreover, a demonstrator will attract scores of listeners who would pass a silent exhibit unnoticed.

MEDICAL WARES

A doctor's success depends largely on the medical wares which he uses. His instruments and office equipment, his books and his medical journals, his automobile and his clothes are parts of his personality, for a physician is known by the tangible work of his tools. A doctor without a well equipped office is like one whose mind is not well furnished with medical information.

Medical research is constantly adding new information and new instruments for applying it. Medical schools and medical societies are insistent in urging physicians to apply themselves to graduate courses of study in order to keep their mental equipment up to date. Doctors are also offered graduate courses in medical wares without cost and in their own offices. It happens that the manufacturer of medical wares has a financial interest in their sale and use, and he is therefore willing and anxious to come to the doctor and instruct him in his own office. Every doctor has a list of salesmen whom he respects for the extent and reliability of the information which they bring.

The manufacturer also uses the pages of medical journals in order to inform the doctor of his wares—their standards of excellence and the scientific methods of their use. Manufacturers and dealers are constantly raising the scientific standard of the literature which they supply to the advertising pages of the *NEW YORK STATE JOURNAL OF MEDICINE*, and are sincerely grateful for the same kind of editorial advice that is given to the authors of scientific articles. The advertising pages of a medical journal are essential for the graduate education of physicians in medical wares and their use.

A third method of graduate instruction in medical wares and their use is that of exhibits at meetings of medical societies. An outstanding example of such an exhibit was that at the annual meeting of the American Medical Association in Philadelphia last June. There a whole floor was given to those of a purely scientific nature, and another to commercial exhibits—and both were conducted in accordance with the strict standards of medical ethics. Doctors absorbed information regarding the use of baby foods and ray machines and the newer publications as eagerly as they did the information given in the scientific exhibits on how to treat rheumatic heart disease and how to estimate the sugar in the blood of a diabetic. There is no dividing line between the exhibits in medical wares and those in the scientific department.

It is the policy of the *NEW YORK STATE JOURNAL OF MEDICINE* to recognize manufacturers and dealers in medical supplies as essential in the practice of scientific medicine. The Journal accepts articles on commercial products, and has conducted an editorial department on the subject of medical wares which it is ready to renew when it receives the proper papers written from a scientific standpoint.

The subject of medical wares is closely connected with that of medical economics, and finances are entirely compatible with science and ethics. Those who are directly concerned with the management of the *NEW YORK STATE JOURNAL OF MEDICINE* recognize the advertisers and exhibitors as friends of the medical profession and essential supporters of scientific research and the practice of medicine.

LOOKING BACKWARD

This Journal Twenty-five Years Ago

The Reorganized State Society. This Journal of January, 1907 contains the following editorial on the first year of the new State Society, which had been formed by the union of the two rival societies:

The *de jure* unification of the profession of the State was accomplished a year ago, the *de facto* unification has gone on continuously ever since and this annual meeting will be a proof of the solidarity of the reorganized State Society and of the wisdom of reorganization.

"The county societies have already felt the impulse of the new regime and the quickening influence of the larger advantages of membership has contributed much to the prosperity of these organizations. The day is here when every reputable physician must affiliate himself with his county society. The combination of these societies into the State Society represents an influ-

ence so potent for the protection of the people of the State and a power so great for the conserving of the interests of the medical profession and the fostering of high standards in medical practice that no sincere physician can afford to withhold his sanction or aid. The doctor who desires to serve the State and his profession can best do so by becoming a part of the organized effort which has that service as its aim. The doctor who desires the improvement of the conditions of medical practice and the mitigation of the evils which hamper his work can best serve his personal interests by becoming a part of the great movement which makes for these ends. Every member of the county society should feel it his duty to urge upon his unaffiliated neighbor the importance of his joining with the whole profession. He has a field of missionary usefulness very near at home."

MEDICAL PROGRESS

Electrical Treatment of Neuritis and Writer's Cramp.—On the basis of an experience of nearly 100 cases W. Black Jones recommends the galvanic treatment of neuritis and writer's cramp. He employed a slight modification of the method advocated by Naughton Davies some thirty years ago. The faradic current is so regulated that it will excite pain in the diseased spot, but will not cause pain in a healthy nerve. When a spot is touched with the electrode and pain is felt, the position is marked. For the treatment the galvanic current is used. An insulated needle is connected with the negative pole, the large pad being positive. A local anesthetic is injected under the dermis, the needle is inserted, being directed to the most painful point, and the current is turned on. The amount of current used does not exceed 1 milliampere, frequently it is 0.2 of a milliampere. Five minutes duration is sufficient for the treatment. Two painful spots are often treated at one sitting. Generally where only one or two spots occur on a particular nerve the current gives immediate and permanent relief. Three patients with writer's cramp came under the author's observation, the most severe being that of himself; in two the condition was mild and responded easily to the treatment. In his own case eleven points were treated on the right forearm. Improvement was at first very slow. Tincture of iodine was administered and massage was applied. In a few weeks movement improved, and later the whole trouble gradually cleared up and there had been no recurrence. When the number of spots is multiple, and they are close together, relief is often only partial, and then the internal administration of iodine is of assistance. —*British Medical Journal*, September 19, 1931, ii, 3689.

The Poisoning Appendix.—James McDonnell presents investigations into the histories, together with roentgenographic findings, in 18 cases of acute appendicitis which suggest that our views on appendicitis should be recast. Instead of visualizing appendicitis as acute or subacute, to be followed by chronic disease, we should realize that the first evidence of trouble in the appendix is made manifest by nebulous symptoms which cannot be accounted for by any other than a toxemic origin. The clinical picture is one of symptoms arising from a condition of either slow general toxicity—e.g., lassitude, general malaise, loss of energy—or one of a more advanced toxemic state showing pyrexia, with the additional complication of vomiting, should a subacute local inflammation of the peritoneal tissues have oc-

curred. None of the author's patients have had pain, tenderness, or discomfort in the right iliac fossa, except when pressure has been applied to a full cecum during x-ray examination. The "poisoning appendix" gives a physical sign which has not hitherto been described, namely, increased resistance of the upper segment only of the right rectus, in an otherwise normal abdomen. This resistance is not easily appreciated, but does not in any way simulate the form of resistance found in epigastric lesions. The roentgenological evidence in these cases can be summed up in the expression "a non-functioning appendix"—an appendix which, on account of some pathological changes, will not fill, or, per contra, will not empty within the somewhat elastic time limit accepted as being the rate of filling or emptying of normal appendices; or one of which the outline or limitation of movement is due to obstruction from within or without—e.g., concretions, constrictions, kinks, or adhesions. Other causes having been eliminated, a "poisoning appendix" is a non-functioning appendix, with a toxemic symptomatology for which the only treatment is appendectomy. Investigations into the histories of patients with acute appendicitis have invariably shown evidence of toxemic origin over a period, either long or short, before the onset of acute symptoms. Acute appendicitis must, therefore, be regarded as a preventable calamity, not as a "bolt from the blue."—*The Lancet*, September 12, 1931, ccxxi, 5637.

Treatment of Migraine with the Anterior Lobe of the Hypophysis.—Irma Klausner-Cronheim reports that she has treated a number of cases of migraine with anterior lobe of hypophysis administered orally. She avoided treatment with injections except in one case, as she wished to exclude the known effect of parenteral administration of protein. All the patients were persons of active mentality, who had never succeeded in aborting an attack when it made its appearance. The dosage was as a rule 1 tablet 3 times a day, being the equivalent of 450 units of anterior lobe. In 3 cases the results were negative; in 7 they were unequivocally good. The attacks either stopped or were so much weaker and less frequent than before that the patients regarded themselves as greatly benefited. Four of the patients thus improved or cured experienced no secondary effects; the other 3 developed some menstrual disturbances which made it seem advisable to reduce the dosage at times or to stop treatment altogether. Any purely suggestive effect of the treatment can safely be excluded.

since these were patients who had been treated in the most various ways previously, and who had a quite natural intense distrust of the value of any kind of therapy. It cannot be said with certainty to which of the hormones contained in the anterior lobe the effect of the treatment is attributable. But since, as Zondek has shown, one hormone, called prolán B, is never present in the climacterium, and since one of the most significant cases was in a woman at this period, it seems probable that it is the hormone called prolán A which is responsible. This would agree with the fact of experience that in men too at the age in which migraine attacks are wont to stop, the latter hormone is demonstrable in the urine. That 7 of the 10 patients responded well to the treatment demonstrates that the theoretical basis from which the author took her point of departure was a correct one. The reason for the complete failure in the other 3 cases may be that while there was the same symptom-complex, the nature of the affection present may have been different in essence. The administration of anterior lobe is not advisable under all circumstances, because of its effect upon the ovaries. The author did not venture to employ it in children or in young girls around the age of puberty, fearing that a sexual precocity or too strong a sexual excitement might be the result. Even in later years the hormone may cause disturbances in the sexual function.—*Deutsche medizinische Wochenschrift*, August 21, 1931.

Fracture of the Neck of the Femur in the Aged: The Over-Slung Traction Saddle a Substitute for Plaster Spica.—In pointing out the defects of the usual methods of treatment of fracture of the femur in the aged, Earl D. McBride states that even the Whitman method, which is scientifically sound as a surgical procedure, requires the use of an anesthetic which seriously jeopardizes the physiological reserve of the patient. He has devised a modification of the Bradford frame and the Jones abduction splint which makes possible suspension of the legs and traction without cumbersome splinting and has the following advantages: The fracture is reduced anatomically and thoroughly, without an anesthetic or without any physical strain on the constitution. Fixation in abduction, internal rotation, and extension is constant. Traction is added to fixation. The sitting posture is possible. The frame may be used as a stretcher in transporting the patient. The frame offers no obstruction to the taking of an x-ray. The knee does not get stiff and the hip retains much of its normal range of motion. The apparatus consists of two sections forming a rectangular frame. The upper section contains an adjustable headrest and a canvas sheet for support of the torso. The lower section is attached to the upper section at the level of the hips by two upright bars and is suspended out

over the legs. Attached to this section are two adjustable angle-iron arms, from which the legs are suspended in muslin hammocks or by straps attached to the pulley rope. Countertraction is secured by two stirrups of padded duraluminum attached by webbing straps to the crossbar above the hips and buckled to the canvas sheet on which lies the trunk. The leg is not manipulated and the position of election is gradually attained by frequent adjustments of the leg bar and pulleys. The duration of immobilization does not differ from that of the cast treatment.—*Southern Medical Journal*, October, 1931, xxiv, 10.

The Spontaneous Cure of Malignant Neoplasms.—In an age in which the etiology and pathogenesis of malignant neoplasms are still obscure, there is no justification, says Mariano Cusani, for rejecting without investigation certain observed clinical facts which point to the possibility of the spontaneous regression of such tumors. He has recently had under his care a man of 65, of robust constitution, who had upon the antero-inferior aspect of the dorsum of his right foot a lesion which had the macroscopic and clinical character of an epithelioma, and which was confirmed as such by biopsy. The patient refused operation, and was accordingly treated with topical medication and sterile gauze dressings applied to the bleeding surfaces. After the lapse of 2 months this entirely negative form of therapy was followed by a regression of the process: there was a gradual decrease of the extensive ulcerated zone, with formation of new epidermis at the borders. A second biopsy was now performed, and at the end of 6 months, when epithelization was complete, a third was carried out. It was thus possible in a series of biopsy examinations to compare the different stages of involution of the neoplastic process, which ended in a definitive finding of practically normal epidermis. We have to admit that the defensive forces of nature, whether endogenous, congenital, or acquired during the course of years of immunization following repeated attacks of fever and of local and general infection to which every growing organism is more or less subject, are so extraordinarily great as to exceed the bounds of our imagination. They include organic humoral conditions, the biochemical constitution of the cell, nervous factors, etc., capable of providing resources still undreamed of, and of awakening such aggressive activity against a local or even a relatively generalized process as to justify fully the concept of a spontaneous cure even of a tumor whose character is malignant. The fact that no form of treatment was applied that could logically overcome the blastomatous stimulus shows that if this stimulus ceased or even diminished, such effect was due solely to the defensive power of the organism.—*Riforma medica*, August 10, 1931.

Measles Serum.—In an article on the "Prevention and Control of Measles, Scarlet Fever, and Diphtheria in Institutions and the Home," David N. Nabarro and A. Gordon Singy report their results with the prophylactic use of convalescent measles serum in 625 children. In this series 98.1 per cent of the children were apparently protected, while in Gunn's series protection was afforded in 95.7 per cent of the cases. These figures give striking and sufficient proof that, until an efficient animal serum is prepared, convalescence measles serum is the best weapon at our disposal for preventing measles, and should be more widely used than it is at present. In the few cases in which the serum failed to protect, the attack of measles was very mild. As children are not suitable donors of adequate quantities of blood, the authors obtained their supply from adults, only normal uncomplicated cases of measles being utilized for this purpose. The greatest care was taken to exclude the possibility of any other infection, particularly syphilis or tuberculosis. From seven to fourteen days after defervescence patients were bled aseptically to the extent of 200 to 400 c.c. into sterile oxalate solution, this procedure yielding as much as 60 per cent of serum, after precipitation of the oxalate with calcium chloride. After testing the serum for a Wassermann reaction, 0.5 per cent phenol was added and the serum pooled with several other serums, to ensure a uniform potency of the final product. In order to ensure the production of complete protection, the authors have increased the dose of serum to 5 c.c. intramuscularly for children under three years of age and to 7 c.c. for those over three. Injected before the fifth or sixth day of incubation, the serum affords complete protection; injected on the sixth to the ninth day of incubation, protection is only partial, and a very mild attack of measles usually ensues. If injected after the ninth day, no benefit may be expected from the serum. Whole blood may be used instead of serum, in which case the blood of a convalescent is injected intramuscularly into the recipient, the amount injected being double the serum dose.—*British Medical Journal*, October 3, 1931, ii, 3691.

Results of the Use of Stramonium in Parkinson's Disease and Postencephalitic Parkinsonism.—O. J. Menard and L. M. Hurxthal report their experience with the use of stramonium in 23 cases, a few of which seemed to be cases of true Parkinson's disease. Only the powdered leaves, at first in capsules, then later in pill form, were used. No worthwhile results can be obtained in giving less than 5 to 7 grains per day. At first $2\frac{1}{2}$ grains are administered three times a day; later this dose may be raised or lowered as seems necessary. A few of the patients took as much as 15 grains a day, and one took $22\frac{1}{2}$

grains. At first most of the patients complain of dryness of the mouth and visual disturbance. The use of citrus fruits or candy helps to offset the excessive dryness. No harmful effects from the drug have been noted. Muscular rigidity, mental retardation, and excessive salivation are almost invariably relieved. Tremor and oculogyria may be lessened. The masked facies and stare are rarely changed, although there may be a distinct change in the countenance, conveying the impression of a more optimistic state of mind. Of the 23 patients in the group, 6 experienced marked improvement, 6 moderate improvement, while 6 received slight benefit, and 4 obtained no help from the drug. The authors conclude that stramonium in adequate doses is helpful in alleviating some of the symptoms of Parkinson's disease and postencephalitic Parkinsonism, and should be tried in all such cases.—*New England Journal of Medicine*, October 15, 1931, ccv, 16.

The Course, Diagnosis, and Treatment of So-Called Chronic Appendicitis.—The expression "chronic appendicitis," according to Albert Oppenheimer, embraces a number of different anatomic and functional changes in the region of the appendix which the roentgen ray alone can present objectively. This is the only method that can establish in each individual case the kind of disturbance present, whether, for example, the condition is one of irritation or is due to adhesions, and if the latter is the case, in what way these interfere with the normal mechanism. The demonstration of cicatrices in the appendix is by no means enough for a diagnosis; functional disturbances must also be present, to justify one in incriminating this organ. Three cases of chronic appendicitis are outlined, all having in common the fact that disturbances supposedly "nervous" had existed over a number of years without any acute attack until a fulminating attack suddenly necessitated appendectomy. Every unfilled appendix and, still more, every appendix too slow in emptying is open to suspicion. When the roentgen picture shows either one of these, one should think of adhesions; but the diagnosis must not be made if there is free mobility with complete absence of functional disturbances. What the roentgenologist has to show in the appendix is cicatricial changes or their functional sequels. Not the establishment of isolated organic lesions, but the pathologic function following these is what determines the nature of the disease. A cicatrix is not a disease until it interferes with function. In chronic appendicitis the manifold localizations of the pains, their varying intensity and the more diffuse sensations that are not localized at all are explained by the widely separated points of attachment of periappendicular adhesions. A deformed appendix may give rise to the most varied clinical symptoms, such

as spasm of the cecum, the sigmoid, or the pylorus; the author has even seen a total spasm of the transverse colon due to the condition of the appendix. Less frequently are states of irritation of the mucous membrane and musculature of the large intestine recognized in the picture of atypical movements. The roentgen findings give precise indications for treatment. Stasis in the appendix always calls for appendectomy. Retention, affecting the cecum also, should be treated with laxatives (paraffin). If spasm predominates (pylorus, colon, colitis symptoms) bland diet and atropine often bring relief until some fresh attack makes operation necessary.—*Deutsche medizinische Wochenschrift*, September 18, 1931.

Progressive Exophthalmos Following Thyroidectomy; Its Pathology and Treatment.—Howard C. Naffziger, writing in the *Annals of Surgery*, October, 1931, xciv, 4, finds that there is no concurrence of opinion as to the underlying mechanism of the exophthalmos which is characteristic of certain types of goiter and which occasionally persists after thyroidectomy. The following case, he believes, throws some light on this subject. In a woman, 47 years of age, protrusion of the eyeballs increased after thyroidectomy. She became nearly blind, the optic discs became choked, and there was a considerable degree of optic atrophy. It was felt that decompression of the orbit offered both an opportunity to relieve the exophthalmos and perhaps to determine its cause. When the orbital fascia was opened and the orbital contents were exposed it was found that the tension of the extraocular muscles was extreme, and it was felt that the explanation of the exophthalmos must lie here. On deepening the incision it was found that instead of a normal muscle, perhaps 1.5 mm. in thickness, there was a deep mass of muscle filling the entire retrobulbar space. Muscle splitting was continued backward until the optic nerve was exposed, and the muscle became progressively more fibrous and even gritty. Following complete decompression of the orbital contents and the optic nerve, the eye receded markedly. At the end of a week it was found that vision was returning rapidly, and in a short time the patient was able to read addresses on letters. She returned a month later, insisting that the same operation be performed on the opposite side. The second operation was equally as successful as the first. Portions of the extraocular muscles on both sides were removed for microscopic examination, which showed round-cell infiltration, marked edema, destruction of the muscle fibers, complete loss of muscle architecture with increase in fibroblasts and generalized fibrosis. In speculating as to the cause of this condition, the author notes that most of the patients described in the

literature as suffering from progressive exophthalmos have had abnormal or low basal metabolism. In the case here reported the basal metabolism was low and thyroid had been given. Kunde has reported that exophthalmos can be produced in rabbits after thyroidectomy by feeding thyroid. It is also noted that in the patient both jugulars had been tied. The fact that the venous return from the orbit had a double channel to the systemic circulation, one by the intracranial route, and the other through communicating veins to the facial vein, might have been one factor in the production of the protrusion.

Agranulocytosis and Aplastic Anemia as Varieties of Bone-Marrow Failure.—F. Parkes Weber, writing in the *Practitioner*, October, 1931, cxxvii, 5, holds that aplastic (hypoplastic) anemia should properly signify any anemia due to deficient formation of red cells in the bone-marrow. Deficient production of red cells is usually accompanied by deficient production of other blood elements derived from the bone-marrow, namely, the granulocytes and the thrombocytes. Between the blood pictures of agranulocytosis and aplastic anemias there are no well defined boundaries, and the blood picture of agranulocytosis may terminate as one of aplastic anemia. Aplastic anemia may be due to old age or exhaustion, to a septic process or a toxin (arsenobenzol, benzol poisoning, etc.) or to both combined, and the same causative factor may be followed sometimes by the blood picture of agranulocytosis, sometimes by that of aplastic anemia. Another reason for regarding agranulocytosis as a variety of aplastic anemia is that in some stages of lymphatic leucemia the blood picture may show hypoplastic anemia, as in a case here described. At one time it was suggested that all patients with acute aplastic anemia, without obvious cause, were in reality in a stage of acute lymphatic leucemia with a fatal termination before the typical changes in the blood picture had developed. This can no longer be maintained since patients with aplastic anemia may be kept alive by blood transfusions for indefinite periods. That x-rays or radium may cause aplastic anemia and agranulocytosis is shown by various published accounts. To these the author adds a case of Hodgkin's disease in which x-ray treatment was responsible for the development of aplastic anemia, and says he would hesitate to advise the same treatment in a similar case. He suggests the use of blood transfusion for aplastic anemia caused by x-rays or radium. He also cites a case in which the application of radium was followed by extraordinarily rapid generalization of a lymphosarcoma-like growth. This case may possibly have been one of Hodgkin's disease in which enlarged lymph glands at times present a lymphosarcomatous appearance.

LEGAL

FEDERAL AND STATE TAXATION OF GIFTS MADE PRIOR TO DEATH

By LORENZ J. BROSNAN, Esq.

Counsel, Medical Society of the State of New York

The enormous expenses of our State and Federal governments have led to constant endeavors to devise legislation by which taxes may be imposed to provide additional and adequate revenue to meet the expenses so incurred. A very clear illustration of the trend in our tax laws is found in those statutes, both State and Federal, which seek to tax gifts made by a decedent prior to his death.

These statutes fall into two classes: First, those which create an artificial presumption that every gift or transfer made by a decedent within a certain number of years of his death shall be deemed to have been made in contemplation of death, and hence be taxable as part of his estate. With the meaning of these statutes, a gift causa mortis or in contemplation of death is a gift of property made by the donor who, at the time of the making of the gift, is in imminent expectation of death and makes the gift mindful of the expectancy of death in the near future. The presumption created by such statutes can, of course, be rebutted by proof that at the time of the making of the gift the donor was not in danger of death and did not make the gift with the expectancy that he was going to die in the near future.

The second class of statutes dealing with the subject under consideration makes a transfer of property in excess of a certain sum, within an arbitrary limit prior to death, absolutely taxable. In other words, in this class of statutes the tax does not depend upon whether or not in fact the donor was in danger of death; and even if proof could be offered that the donor was at the time of the making of the gift in perfect health, under these statutes if the gift is made within a certain time prior to death it is taxable as part of the estate of the donor. The statutes in question represent the natural development of attempts to evade and avoid the tax on decedents' estates through the medium of gifts prior to death.

In the State of New York the pertinent provision of our tax law reads as follows:

"Any transfer of a material part of his property made by the decedent within two years prior to his death, without such consideration shall, unless shown to the contrary, be deemed to have been made in contemplation of death within the meaning of this article;***" (Tax Law, Sec. 249-r.)

It will be noted that under this statute the presumption there created may be rebutted by proper

proof. With respect to the constitutionality of such an enactment the Supreme Court of the United States has said:

"***the establishment of presumptions and of rules respecting the burden of proof, is clearly within the domain of the state governments, and that a provision of this character, not unreasonable in itself and not conclusive of the rights of the party, does not constitute a denial of due process of law."

As illustrative of how far some States have gone in their endeavors to place a tax upon transfers made at any time prior to death, it is interesting to consider a statute of one of our mid-Western States passed a few years ago. This statute declared, in substance, that all gratuitous transfers of a material part of a decedent's estate made within six years prior to death should be treated and taxed as though made in contemplation of death. This statute, unlike the statute in New York, did not merely create a presumption but laid down the arbitrary rule that all gifts made six years prior to the decedent's death were taxable as gifts made in contemplation of death. Under this statute it was not possible to introduce proof showing that the donor was in perfect health and that the gift was not made in expectancy of death in the near future. The constitutionality of this statute was challenged on the ground that it was violative of those clauses contained in the Fourteenth Amendment of the Constitution of the United States guaranteeing due process of law and equal protection of the law.

The Supreme Court of the United States, dealing solely with the statute in question, held that to tax gifts within a six-year period of time was to deprive the donees of their property without due process of law, and that the statute did not afford to them the equal protection of the law. The court was divided on the question, Mr. Justices Holmes, Brandeis and Stone dissenting from the majority opinion. The dissenting opinion of Mr. Justice Holmes is important in the light of the Federal statute which we will discuss in this editorial. The dissenting opinion said in part:

"If the Fourteenth Amendment were now before us for the first time I should think that it ought to be construed more narrowly than it has been construed in the past, but even now it seems to me not too late to urge that in dealing with State legislation upon matters of substantive law we should avoid with great caution attempts to

substitute our judgment for that of the body whose business it is in the first place with regard to questions of domestic policy that fairly are open to debate

The present seems to me one of those questions I leave aside the broader issues that might be considered and take the statute as it is written, putting the tax on the ground of an absolute presumption that gifts of a material part of the donor's estate made within six years of his death were made in contemplation of death. If the time were six months instead of six years I hardly think that the power of the State to pass the law would be denied as the difficulty of proof would warrant making the presumption absolute, and while I should not dream of asking where the line can be drawn since the great body of the law consists in drawing such lines, yet when you realize that you are dealing with a matter of degree you must realize that reasonable men may differ widely as to the place where the line should fall. I think that our discussion should end if we admit, what I certainly believe, that reasonable men might regard six years as not too remote. Of course many gifts will be hit by the tax that were made with no contemplation of death. But the law allows a penumbra to be embraced that goes beyond the outline of its object in order that the object may be secured. A typical instance is the prohibition of the sale of unmixing malt liquors in order to make effective a prohibition of the sale of beer. The power is not to be denied simply because some innocent articles or transactions may be found within the proscribed class. In such cases and they are familiar, the Fourteenth Amendment is invoked in vain. I am not prepared to say that the legislature of Wisconsin, which is better able to judge than I am, might not believe, as the Supreme Court of the State confidently affirms, that by far the larger proportion of the gifts coming under the statute actually were made in contemplation of death. I am not prepared to say that if the legislature held that belief, it might not extend the tax to gifts made within six years of death in order to make sure that its policy of taxation should not be escaped. I think that with the States as with Congress when the means are not prohibited and are calculated to effect the object we ought not to inquire into the degree of the necessity for resorting to them.

"It may be worth noticing that the gifts of millions taxed in this case were made from about four years before the death to a little over one year. The statute is not called upon in its full force in order to justify this tax. If I thought it necessary I should ask myself whether it should not be construed as intending to get as near to six years as it constitutionally could and whether it would be bad for a year and a month."

The Federal Revenue Act of 1926 contains similar provisions to those embodied in the stat-

ute just discussed, except that instead of a six-year period the Federal Act reduces the period to two years. The tax is not based on any presumption, but is an absolute tax not capable of being rebutted by proof that the gift was not made in contemplation of death. This statute provides

"Where within two years prior to his death*** the decedent has made a transfer*** not admitted or shown to have been made in contemplation of or intended to take effect in possession or enjoyment at or after his death, and the value or aggregate value, at the time of such death, of the property or interest so transferred to any one person is in excess of \$5,000, then to the extent of such excess, such transfer or transfers shall be deemed and held to have been made in contemplation of death within the meaning of this chapter."

Within the last year this statute has been the subject of attack on the ground that it is unconstitutional in three cases in the lower Federal courts, and in each case the court held the law unconstitutional. The facts before the courts in these decisions illustrate the operation of the statute.

In the first case the deceased, within two years of his death, had made a wedding gift of certain securities to one of his daughters and at the same time had given a like amount to another daughter. There was no evidence that the gifts were made in actual contemplation of death. The collector of internal revenue assessed a tax upon the gifts, and suit was brought to recover the amount paid under protest. The court ruled that the section of the act under which the tax was imposed was unconstitutional.

Within a few days another district court made a similar ruling. In that case the decedent had died in December, 1928, having in 1927 made certain advancements to his sons evidenced by notes. In the suit to recover the amount of a tax paid under protest, the collector conceded that the gifts were complete and irrevocable gifts by the decedent to his children during his lifetime which were not made in contemplation of death, but contended that they were taxable under the statute.

In the third case, which arose in one of the district courts of this State and was decided but a few months ago, the action arose out of a transfer by the decedent a little less than a year and a half before his death, of a half-interest in a piece of real estate in New York City to his son. The record showed that the gift was not made in contemplation of death, but as a provision for the son upon his marriage. The judge decided that the tax paid under the statute should be refunded, stating that the statute was unconstitutional as having fixed a purely arbitrary period of time, and working as a tax upon a gift without regard to the facts or the actual intent

Unless the law is in the meantime repealed, the validity of this tax is almost certain to be ruled upon eventually by the Supreme Court of the United States. The ruling by the court already referred to, declaring unconstitutional a

statute where a six-year period preceding death was involved, is not necessarily conclusive on the question of the present Federal statute which limits taxation to a period of two years preceding death.

ALLEGED NEGLIGENCE IN TREATING FRACTURE

A man about fifty-five years of age received an accidental injury to the lower third of his left leg near the ankle, as a result of a kick from a horse. Immediately after the injury, a nearby general practitioner was called to attend him and upon examination found the leg to be in a very serious condition, the injury appearing to be a compound fracture of both bones of the leg and both bones being shattered. The doctor placed a temporary splint on the leg, put the patient in his car and drove him to the nearest hospital. X-rays were immediately taken and disclosed a compound comminuted fracture of the tibia and fibula.

A surgeon who specialized in the treatment of fractures was called in to take charge of the case. He examined the leg and the X-ray pictures, and informed the patient that the fracture was such an extremely bad one that better function of the leg would probably result from amputation. The patient refused to consent to an amputation and thereupon he was put under a gas ether anesthesia, and with the aid of a fluoroscope the surgeon, assisted by the general practitioner, as best he could under the circumstances reduced the fracture, moulding the bones into the best possible position. A forcible extension of the leg was undertaken and a light plaster of Paris cast was applied after the foot and leg had been well protected and padded with sheet wadding, and the wound cleaned thoroughly with alcohol and iodine. The cast covered the whole foot and leg and extended well above the knee. A window was provided in the cast over the point where the flesh was lacerated by the protruding bone.

The plaintiff then remained in the hospital for several days under the care of the surgeon. During the entire time of his stay at the hospital the patient continually requested that he be permitted to go home to convalesce so that he might avoid the expense of hospitalization. The patient's progress was extremely good under the circumstances; no evidence of sepsis or suppuration developed in the wound.

At the end of nine days, at the insistence of the patient, the surgeon permitted him to be

removed to his home with explicit directions that he should immediately place himself under the care of the first doctor for further observation and treatment. The patient did not communicate with said doctor for nearly three weeks, when the doctor promptly called at the patient's home and examined the leg. He found that the wound had healed, and removed the upper part of the cast for the patient's comfort. About a week later the doctor again called and removed the rest of the cast and bandaged the ankle carefully for support, at that time warning the man not to undertake to place any weight on the leg for some time and, if he attempted to walk, to do so with the aid of crutches.

The doctor returned a few days later and found that the patient had moved from the locality. The next he heard of the case was about six months later when the patient called at his office to solicit aid from the doctor that he might enter the county home. At that time examination disclosed that the leg was in very good condition considering the nature of the injury.

Nearly two years later an action was started against both of the doctors in question, in which it was claimed that due to their negligence in setting the fracture the plaintiff's leg became stiffened, permanently malformed and shortened. It was also claimed that as a result of the negligence and malpractice of the defendants the plaintiff had been unable to perform any work and had become dependent upon charity for his support. When the action came on for trial before a judge and jury, the plaintiff appeared in court with his leg somewhat misshapen, but he was able to walk upon the same with a very slight limp. The plaintiff failed to present any medical testimony to the effect that either of the doctors had in any way departed from proper practice in their treatment of the patient, and upon the motion of the attorney for the defendants the complaint was dismissed at the close of the plaintiff's case, thereby terminating the matter in favor of the doctors without requiring them to put in their defense.

NEWS NOTES

REPORT OF THE JOINT COMMITTEE TO STUDY THE REPORT OF THE GOVERNOR'S SPECIAL HEALTH COMMISSION AND MAKE RECOMMENDATIONS UPON ALL OR ANY OF THE SUBJECTS PRESENTED

To the House of Delegates:

Organization

In accordance with your instructions given at your last annual meeting that "the Committee on Public Health and the Committee on Public Relations study the report of the Governor's Special Health Commission and make recommendations upon all or any of the subjects presented and that the said committees report their recommendations to the House of Delegates not later than January 1, 1932," these two committees met in Albany in the office of the Legislative Bureau on September 11, 1931, and after deliberating upon the instructions, decided that you intended the two committees should combine and undertake the study as a joint committee. Accordingly, each committee met separately and voted in favor of such action. The two committees then organized as a Joint Committee which hereafter shall be the term used in referring to the committees in this report. Dr. Thomas P. Farmer was elected Chairman, and Dr. Joseph S. Lawrence, the Executive Officer of the State Society, was elected Secretary. The Joint Committee granted Dr. William H. Ross' request, transmitted through Dr. James E. Sadlier, that Dr. Ross, although a member of the Public Relations Committee, be excused from sitting with the Joint Committee for the reason that he is a member of the Governor's Special Health Commission. At the next meeting a sub-committee was elected, consisting of Dr. Farmer, Dr. Sadlier and Dr. Lawrence, to arrange details of the meetings of the committee and such other necessary matters as had to be transacted between the meetings of the committee.

Definition of Scope

The Joint Committee decided that its scope of study should include; (1) the Preliminary Report of the Governor's Special Health Commission dated February 19, 1931, and known as Legislative Document Number 65 of 1931, and which hereafter will be referred to as the Preliminary Report; (2) any legislation bearing upon the report; and (3) such other matters as appear in the minutes of the House of Delegates (Section 41) of the annual meeting of the State Society on June 1, 1931, in the discussion preceding the adoption of the resolution directing this study.

Methods of Study

After careful deliberation the Joint Committee decided that it could best obtain information for its study from four sources:

1. The Preliminary Report of the Governor's Special Health Commission.
2. Members of the Governor's Special Health Commission.
3. Individuals well informed and experienced with the subjects or activities considered in the Preliminary Report.
4. Representatives of county medical societies.

The sections of the Preliminary Report were assigned to individual members of the Joint Committee for intensive study. The following members of the Governor's Special Health Commission, upon invitation, appeared before the committee: Dr. Livingston Farrand, Commissioner Thomas Parran, Jr., Dr. George W. Cottis, Dr. Matthias Nicoll, Jr., Dr. Linsly Williams, and Mr. Homer Folks. Dr. William H. Ross was invited as a member of the Governor's Special Health Commission, but was unable to be present. Dr. Edward L. Keyes was invited as a member of the Governor's Special Health Commission, but was unable to be present and requested that the Joint Committee invite Dr. William F. Snow, a member of the Sub-Committee on Social Hygiene of the Governor's Special Health Commission. Dr. Snow was, therefore, invited and appeared before the Joint Committee. The following persons were asked to appear before the Joint Committee because of their special knowledge of and experience in certain health subjects or activities: Dr. Burton T. Simpson, Director of the State Institute for the Study of Malignant Disease; Dr. Daniel R. Reilly, Commissioner of the Cortland County Health Department; Dr. Arthur T. Davis, Commissioner of the Suffolk County Health Department. Dr. Reginald M. Atwater, Commissioner of Health of Cattaraugus County, was invited but was unable to be present. The president and secretary of each county medical society were notified of the times and places of meetings of the Joint Committee, at which a report from their county society might be presented. Statements either through personal representation or by correspondence were received from all county medical societies except Columbia, Delaware, Fulton, Livingston, Oswego, St. Lawrence and Schuyler.

Meetings

The Joint Committee has held eight regular meetings. The first two were devoted to organization, preparation for study, and the consideration of the various sections of the Preliminary Report of the Governor's Special Health Commission. These meetings were held in Albany and New York City. The next four meetings were held in Buffalo, Syracuse, Albany and New York City. The morning session of each of these four meetings was devoted to executive business of the Joint Committee, the Joint Committee's study of the report of the Governor's Special Health Commission, and hearings for members of the Commission and other persons especially invited by the Joint Committee. At the afternoon session of each of these meetings one member of each county medical society represented was heard by the Joint Committee, after which all members from county medical societies represented were given an opportunity to speak. The subsequent meetings of the Joint Committee have been concerned with the correlation of all the data obtained by the Joint Committee and formulation of its conclusions. A complete record of the proceedings and hearings of the Joint Committee has been prepared and filed with the secretary of the House of Delegates.

Study of Report of Governor's Special Health Commission

The report of the Governor's Special Health Commission which the Joint Committee has studied, is designated a Preliminary Report. The Joint Committee has learned that a complete report is yet to be made by the Governor's Special Health Commission. Your Joint Committee finds that their instructions from the House of Delegates definitely refer to the Preliminary Report as printed, since the wording of the minutes of the House of Delegates is: "Study of the volume that was printed." The Joint Committee reviewed the entire printed volume known as the Preliminary Report, discussing it section by section, and after obtaining as much information as possible, discussed the Preliminary Report as a whole. The Preliminary Report is prefaced by a message to the legislature from the Honorable Franklin D. Roosevelt, Governor of the State of New York, which states reasons why the study was made. The Governor calls attention to the accomplishments in public health work in New York State, making this statement: "The progress which we have made in the last fifteen years is nothing short of phenomenal," and he evidently believes that much of this is due to "legislation passed in 1913 upon recommendation of a state health commission." Calling attention to the piecemeal amendments made to the public health law since 1913, the rapid strides in medical science, and experience gained in public health ad-

ministration since that time, the Governor gives these as reasons for the present study which, in the opinion of the Joint Committee, justifies his decision. As the Governor's letter again refers to the "outstanding achievements and accurate knowledge of modern medical science," it is the opinion of the Joint Committee that the Governor distinctly had in mind the necessity for representation of the medical profession on the Commission. In his letter to the legislature the Governor refers to the recommendation regarding the organization of county boards of health as the outstanding feature. Our study of the Preliminary Report indicates that this recommendation has been the one of greatest importance.

State Aid

The Preliminary Report of the Commission recommends that state aid be continued for the development and operation of county health work. The Joint Committee has given much consideration to this recommendation and also to the general question of state aid. It realizes that state aid may stimulate communities to action earlier than might otherwise be had and that it may be of particular assistance to some communities to obtain service which otherwise they might not secure. The Joint Committee cannot foresee the ultimate limits to which this debatable principle may be extended nor where control may ultimately center. The Joint Committee, therefore, feels that it has not the necessary information to make a definite pronouncement on the general subject of State Aid, but believes this subject is of great importance and merits study by medical, economic and legislative authorities.

Local Health Organizations

The section of the Preliminary Report entitled "Local Health Organizations" considers the advantages of county health units and recommends their organization in all counties. From a study of the report itself, from information obtained from members of the Commission, and from information received from county medical societies, it is apparent that the major feature of the Preliminary Report deals with this particular recommendation. As a result, a large part of the time of the Joint Committee has been occupied with a review of this subject. In considering county health units it must be remembered that the standards of such organizations vary considerably. The Joint Committee has had in mind as desirable only a county health unit which would be efficient, economical and progressive,—an organization which through the cooperation of the medical profession should benefit the community. The State Medical Society approved such an organization at its annual meeting of the House of Delegates on May 9, 1927. The Joint Committee does not feel that establishing county

boards of health without regard to standards is a progressive step.

The Joint Committee, from its study and from information furnished by county medical societies, finds that many of the societies have given this matter serious consideration and that many are making progress toward the inauguration of county health departments of the proper type under the present permissive law. The information obtained from the county medical societies has been instructive and inspiring. Advantages claimed for a properly organized county health unit are: Centralization of authority within the county itself; coordination of health activities within the district; elimination of duplication and overlapping; economies in administration; provision for adequate public health nursing under medical supervision; provision for safeguarding milk and water supplies; better opportunity for proper health education; opportunity for the county medical society to make its services available in an efficient health program.

Objections offered to a county health unit are: Fear of political interference on the part of the governing bodies of the county; possibility of the county health commissioner assuming absolute authority if the county board of health fails to meet its proper obligations and duties, and the possibility of such an organization becoming bureaucratic and invading the field of the practice of medicine. It is interesting to note, however, that some county societies feel that a county health unit is a step away from any bureaucratic organization or the possibility of state medicine. It should be observed that certain county medical societies, while approving the general principle of the county health unit, specifically object to the adoption of this principle in their own counties because of geographical or political conditions, the heavy demands of taxation at the present time due to mandatory conditions or because of expense. In some counties it is feared that the work in outlying districts in unfavorable seasons would not be done as well under a centralized form of administration as under the present method. Objection has been offered in certain counties that public health nurses might exceed their authority. The information obtained from county medical societies indicates that there is no great opposition to the principle of the county health unit, but a majority of those which have expressed an opinion oppose the mandatory proposal.

In view of the advantages offered in favor of a county health department, we believe that the county is a proper governmental area on which to base public health work and that the existing village and township plan is too disconnected and lacks the unity essential for proper administration. Since much legislation is mandatory, we see no reason why a measure which has to do with such a vital problem as public health should not have

the force given it by a mandate. We regret that the Commission could not submit its plans earlier to the leaders, both lay and professional, so that there might have been more time for deliberate consideration and discussion before legislative action was requested. Furthermore, we consider that in a period of great financial depression it may be temporarily injudicious to encourage legislation which of necessity, if it is effective, must entail an additional burden upon the taxpayers.

We are impressed by the fact that several counties are on the point of developing county health departments under the permissive act and we think they should be given a chance to work out such plan in advance of any mandatory procedure. Therefore, whilst we are in definite accord with the recommendation of the Governor's Special Health Commission with reference to the development of county departments of health, we would suggest that the mandatory provision be deferred. With mandatory action deferred we recommend that the Medical Society of the State of New York requests its Public Health Committee to carry on a campaign of education so that the various component county medical societies will become fully acquainted with their duties and responsibilities and be capable of exercising their leadership, which is essential in the development of any public health program. We also recommend that county medical societies encourage the development from their own societies of physicians who may qualify as county health commissioners and thereby preserve the principle of home rule.

Calling attention again to the desirability of home rule, the Joint Committee recommends that some plan be developed whereby small counties might have a commissioner of health of their own selection, possibly by combination with other counties or by formation of a consolidated health district. Your Joint Committee realizes the legal difficulties involved in this recommendation, but is of the opinion that they can be surmounted by proper legislation.

Your Joint Committee strongly emphasizes the desirability of retaining the present local health officer as a deputy under the county commissioner of health.

The Joint Committee is of the opinion that at least three physicians should be members of the county board of health and recommends that the present law be amended whereby county medical societies may have the opportunity of nominating a panel of physicians from which the county board of supervisors may make appointments of medical members to the county board of health.

Regarding any provision for excluding small cities from county health districts or for providing retention of boards of health in villages over five thousand population, your Joint Committee feels that if the advantages set forth for a county health department are well founded, then the en-

tire population is entitled to the benefits of such an organization. Only communities of fifty thousand population or more, or in which a full-time health officer is in charge, should have the option of exclusion from county health units.

The attention of your Joint Committee has been called to the apparent irregular and infrequent meetings of the county board of health in one county. Believing that this fact may be responsible in part for the unsatisfactory conditions under which that particular county board of health is operating at the present time, as well as for many other reasons, we recommend that the present permissive law be amended so as to provide that county boards of health meet at regularly specified monthly intervals.

It has been suggested to the Joint Committee that an advisory board of from three to five physicians (depending on the size of the county) be appointed by the county medical society to advise with the county commissioner of health on such matters as he may desire. Your Joint Committee feels that such an advisory committee would be not only an aid to constructive health work, but would be also an important factor in maintaining harmonious relations between the medical profession and the county health department. The accomplishments to be obtained through such harmonious relationships are well exemplified in the splendid work now being done by physicians in several counties. Your Joint Committee favors the retention of that part of the present law providing for dissolution of county boards of health.

Health Administration in Cities

In regard to health administration in cities, the Joint Committee reports that it is in favor of the principle that full-time health officers be provided for cities of fifty thousand or more population.

Tuberculosis

The main recommendations of the section on Tuberculosis have already been enacted into law. The Joint Committee is in accord with these recommendations. It feels that the counties from which patients come to the new state sanatoria should assume complete financial responsibility for the maintenance of such patients. The Joint Committee regrets that provision for the building of preventoria has not received consideration from the Commission. The importance of managing bone and joint tuberculosis in such a way as to avoid crippling deformities is discussed in this report of the Joint Committee under the heading Orthopedics.

Venereal Diseases

The Joint Committee is opposed to the principle of treatment of non-indigent cases by public authorities. It is in accord with the principle of giving public health authorities control of any

infectious disease while in a communicable stage, but this does not mean that it should necessarily follow that the treatment in such stage should be provided by public health officials. Furthermore, from reliable information obtained, the Joint Committee feels that greater progress will be made in the control of venereal diseases especially in rural and small communities when treatment is given by an individual physician rather than in clinics.

Cancer

The Joint Committee is in accord with the recommendations regarding cancer and suggests the need for maintaining the identity of the State Institute for the Study of Malignant Disease, located in Buffalo, and that provision should be made whereby the qualifications for a director of that institution are not made the same as might suffice for a director of a division of cancer in the State Department of Health. The Joint Committee is conscious of what has been accomplished among the medical profession from an educational campaign directed against cancer and carried on by the Medical Society of the State of New York. Your Joint Committee recommends that educational work either public or professional on the subject of cancer should be done in close cooperation with the Medical Society of the State of New York and the American Society for the Control of Cancer.

Maternal and Infant Hygiene

No disagreement can be found with the statement contained in the Preliminary Report "that among the most vital public health problems of the present day is that of adequate protection of mothers and infants" and "that adequate care during pregnancy and childbirth will save the lives of many mothers as well as reduce materially the deaths among infants in the first months of life."

Improvement in child hygiene and better medical care have brought about a great reduction in the death rates in small children, but other surveys show the undoubted need of more effective methods of detecting errors of growth and development in the pre-school and school child. This requires intimate cooperation between public health agencies and physicians and continued efforts are necessary to secure this.

An effective program of maternity care must be coordinated so as to include every stage of the process from early pregnancy to the restoration of the mother to normal health after delivery. The efforts at providing pre-natal care have unbalanced the scheme of pregnancy supervision, and fault must be found with lay agencies in particular which stress this period to the exclusion of the intranatal and postpartum care. This fact does not appear to be sufficiently or satisfactorily

brought out in the report under consideration. The fact must not be lost sight of that the high death rate associated with pregnancy does not involve alone the classes of our population that would be reached by public agencies. There must be some other factor at work to account for the high death rates associated with childbearing aside from the lack of public clinical facilities. The confirmation was amply brought out at the recent White House Conference and elsewhere, that the improved education of doctors and nurses was one of the most important factors in providing safe and satisfactory obstetric care. It is essential that this be recognized, and this recognition is of greater consequence than the recommendation that adequately organized county-wide health services constitute the most important element in providing the needed services for reduction of the maternal and infant death rates. The function of a health department should be rather of a supervisory character, by establishing standards for proper obstetric practice and by making studies of state wide conditions, the results of which may be applied to the solution of local problems.

School Hygiene

No recommendations are made in the Preliminary Report under the section on School Hygiene. Your Joint Committee is of the opinion that the underlying principle of this section is a satisfactory mutual agreement between the State Department of Health and the State Department of Education. It will be necessary for this mutual understanding to extend to cities and it is to be hoped that the same definition of authority can exist in both state and municipal departments of health and education.

The Joint Committee approves of the principle that school children should be examined more thoroughly and that these examinations should be made frequently. We suggest that efforts be made to develop satisfactory cooperation between the public health authorities and the practicing physicians of the community for the conduct of these examinations and of treatment.

Orthopedics

Of the recommendations in the section entitled Orthopedics, your Joint Committee approves of enlarging the Reconstruction Home at West Haverstraw. We believe that its services should be limited to the unimprovably crippled and to the indigent crippled or handicapped children from counties that cannot develop their own orthopedic services. Furthermore, there could be included those requiring long periods of months or years of educational and corrective treatment, thus taking from the counties particular classes of cases which could not be cared for in their own locality. It is the feeling of the Joint Committee that this section is not properly worded, and that

greater consideration should have been given to the prevention of the onset of disabling conditions as well as their later cure, and that local and private institutions furnishing corrective care should not be hampered by the state's program.

Public Health Nursing

The recommendations in the section on Public Health Nursing are general and indefinite and require no special comment.

Industrial Hygiene

In the section on Industrial Hygiene, three recommendations are made, with the first and third of which the Joint Committee is in accord. The Joint Committee feels that recommendation No. 2, extending the schedule of occupational diseases "to include all diseases arising out of employment and giving authority to make awards in cases of such occupational disease when it is established that the particular disability in fact arose out of employment," needs clarification and further study by a commission.

Sanitation

The Joint Committee approves all the recommendations made under the section on Sanitation, but regrets that the Commission did not give greater attention to the subject of pollution of streams by sewage.

Public Health Personnel

The Joint Committee is of the opinion that the Public Health Council is the proper body to establish qualifications for physicians in public health work wherever required, but that such authority should be given only when positions are created or the necessity arises.

Your Joint Committee also recommends that provision be made in the public health law to require the Public Health Council to hold open hearings upon proposed regulations or changes in the sanitary code before their adoption.

Realizing the importance of authoritative medical representation on the Public Health Council, your Joint Committee recommends the consideration of a plan whereby the State Medical Society shall have the privilege of submitting to the Governor of the State of New York a list of suitable names from which he may make appointments when filling the place of a medical member of the Public Health Council. It is felt that this procedure will be found advantageous to the Governor and to the public.

General Matters

The discussion in the House of Delegates in connection with the adoption of the resolution directing this study mentions general matters regarding the Preliminary Report of the Gover-

nor's Special Health Commission as specific reasons for making this study. In this regard, your Joint Committee offers the following information which it has obtained: In his message to the legislature the Governor has stated amply, as previously mentioned, his reasons for appointing a Health Commission at this time. The Special Health Commission was appointed by the Governor and consisted of fourteen members, eight of whom are physicians. Three of the medical members of the Commission are in active medical practice, two are public health officials, one is a research worker of renown, one is an executive officer of a medical organization, and one is the president of a large university. However, your Joint Committee feels that the question of the personnel of the Commission should not be a matter for or against any real benefits which have been derived from or may grow out of their study. The cost of the study of the Commission was financed by the Milbank Memorial Fund and by a small contribution from the Association of Women's Clubs. The point should be made clear that the Special Commission is a Governor's commission and not a legislative commission.

Present Status of the Public Health

The Joint Committee desires to comment on that portion of the Preliminary Report entitled "Present Status of the Public Health," which it

has studied very carefully. The Joint Committee agrees with the Commission that the "notable progress which has been made in the prevention of sickness and of death has been due to a variety of factors." The Joint Committee cannot agree with the Commission in its last sentence that "Any further progress will depend upon strengthening the weak links in the chain by the establishment of a satisfactory system of local health administration." Further progress in public health, and in the prevention of disease, certainly depends upon a multitude of factors.

The personnel of the Joint Committee is as follows:

Thomas P. Farmer, *Chairman*

From the Committee on Public Health and Medical Education:

Thomas P. Farmer

George W. Kosmak	Martin B. Tinker
Mahlon H. Atkinson	Clayton W. Greene
Leo F. Schiff	Edward C. Whipple
William A. Groat	Nellis B. Foster

From the Committee on Public Relations:

James E. Sadlier

Oliver W. H. Mitchell	George M. Fisher
Augustus J. Hambrook	William H. Ross

COUNCIL MEETING

A meeting of the Council of the Medical Society of the State of New York was held on Thursday, December 10, 1931, in the rooms of the Society in New York City. The business of immediate importance was action on the resolution adopted by the House of Delegates on June 1, 1931, and printed in the Journal of July 1, 1931, page 828, instructing the Committee on Public Health and the Committee on Public Relations to act as a joint committee to study the report of the Governor's Health Commission (see page 1208 of the Journal of October 1, 1931) and to report to a special meeting of the House of Delegates to be called by the Council.

GOVERNOR'S HEALTH COMMISSION

Dr. T. P. Farmer, Chairman of the Joint Committee on the Governor's Health Commission, reported that the Committee had completed its investigations; and that in the near future it would submit a formal report.

The Council decided to call a special meeting of the House of Delegates on Thursday, January 14, at 2 P.M., in the Hotel Ten Eyck, Albany, N. Y., to act upon the report.

The report of the Joint Committee is printed

on page 29 of this Journal, and a reprint has been mailed to every member of the House of Delegates and to every County Society.

GRADUATE EDUCATION

Dr. T. P. Farmer, Chairman of the Committee on Public Health and Medical Education gave a report on the work of the Committee during the Fall, as announced in the program printed in the Journal of November 1, 1931, page 1344.

The work in Graduate Education was described as follows:

"Since July first post-graduate courses have been given in the following county societies with the subjects and number of lectures for each county as listed:

Monroe County (including Livingston, Genesee and Ontario)	Pre-Clinical Medicine	4 lectures
Rockland	Internal Medicine	4 lectures
Cortland	Traumatic Surgery	6 lectures
Schoharie	Dermatology and Syphilology ..	6 lectures
Otsego	Dermatology and Syphilology ..	6 lectures
Seneca	Traumatic Surgery	6 lectures
Wayne	Traumatic Surgery	6 lectures

All of these courses have been completed except those in Schoharie, Otsego and Cortland counties. The course in Cortland County will be completed on December eighteenth. In Schoharie and Otsego counties the lectures are being given once a month so that these courses will not be completed until May, 1932. Because of these facts it is impossible to obtain the detailed information necessary to make the usual statistical comparison of the work of the Committee for the year with the preceding year as has been the custom in the past. In the annual report of the Committee this information will be given.

An innovation is being tried in Schoharie and Otsego counties in the addition of a clinical day to the regular course. In Schoharie County the day is to be given over to the subject of Pediatrics and the clinic is to be conducted by Dr. H. L. K. Shaw. In Otsego County one day in December will be given over to surgical subjects and one day in January to medical subjects. Dr. A. W. Elting will conduct the Surgical Clinic and Dr. Nellis B. Foster the Medical Clinic. On these days the lecturer will not only talk on subjects assigned to him but will give a practical demonstration in examining cases and formulating diagnoses. In a general way the amount of work in graduate education for the first half of this year is about the same as for the preceding two years.

The Committee has already arranged for two courses in its Spring program, one in Sullivan County, and one in Onondaga County. Both of these courses will start shortly after January first.

POLIOMYELITIS

Dr. Farmer also described the work of the subcommittee on poliomyelitis whose organization was described in this Journal of August 15, 1931, page 1048. Dr. Farmer reported:

"The subcommittee considered the question of the collection, control and use of immune serum arrangements for consulting diagnostic service and arrangements for medical meetings at which talks on poliomyelitis were to be given. A letter was promptly sent to officers of all county medical societies, and to the chairman of the Public Health Committee of the same societies, advising them on matters regarding poliomyelitis and requesting the arrangement of special meetings when an outbreak of the disease seemed imminent in their locality. Meetings were immediately arranged for all the county societies in the region of the Hudson River. These meetings were addressed by Dr. Draper, whose services were secured by the State Department of Health. The meetings, however, were arranged by Dr. Shaw for this committee and included the following county societies: Schenectady, Albany, Rensselaer, Saratoga, Warren, Washington, Ulster, Sullivan, Orange, and Dutchess. Putnam. Dr. Aver of Syracuse addressed the counties of

Broome, Tompkins, and Chenango. Dr. Ludlum arranged for a meeting in Kings County and a meeting was held in Nassau County. The reports indicate that these meetings were all well attended and that the activity of the committee met with most favorable reception from the profession especially in the sections where the disease occurred. There is no question but that the committee's efforts in organizing the medical profession brought about excellent cooperation upon the part of the profession with the Health Department in the latter's efforts to control the disease. It is hoped that the Commissioner of Health will later arrange another meeting with the subcommittee on poliomyelitis for the purpose of studying the experience during the epidemic of last summer and with the thought of making recommendations for the control of future outbreaks."

HEALTH EXAMINATIONS

Dr. C. W. Crampton, Chairman of the Special Committee on Periodic Health Examinations, reported that the committee held its regular Fall meeting on October 22nd. The committee had continued its radio work and had broadcast addresses as follows:

November 5, Dr. Walter L. Niles, New York, on "Keeping the School Girl Fit."

November 12, Dr. Thomas P. Farmer, Syracuse, on "Why the Health of the High School Girl Is so Important to Her Future Welfare."

November 19, Dr. Nathan B. Van Etten, on "Modern Medicine for the Modern Girl."

December 3, Dr. Harlow Brooks on "The Importance of Health Examinations for Developing Young Women."

December 10, Dr. John A. Card, "The Greatest Gift."

December 17, Dr. William W. Herrick, "The Periodic Health Examination and The Health Record."

PRESS PUBLICITY

The Council passed the following resolution: "RESOLVED, That the principles governing publicity adopted by the Press Publicity Committee and published in the NEW YORK STATE JOURNAL OF MEDICINE on December 1, 1931, shall be binding upon every member of the Medical Society of the State of New York, and be it also

"RESOLVED, That any member of the Medical Society of the State of New York who knowingly violates those principles or is guilty of a violation of them after warning by competent authority, shall be subject to investigation by the Censors of his county medical society and be subject to such discipline as the Comitia Minora of the County Society may determine."

SCIENTIFIC EXHIBIT AT THE ANNUAL MEETING

Arrangements are being made for a scientific exhibit to be held in conjunction with the annual meeting of the Medical Society of the State of New York, to be held in the Hotel Statler, Buffalo, May 23-25, 1932. Those who wish to participate are urged to send in their requests to the Chairman of the Committee on Scientific Work.

All applications must be received before March 1st. They will be acted upon by March 15th. Notification of acceptance or rejection will be mailed shortly after that date.

Each exhibit must be in charge of a competent, well-informed demonstrator. The exhibits must be completely installed before 9:00 a.m. Monday, May 23rd, and must remain intact until 5:00 p.m. Wednesday, May 25th.

Those whose applications have been accepted will receive a letter of instruction as to the location of their exhibit space.

In sending the application, state the exact title so that it may be published in the program and appear in our Journal. Describe the exhibit so that we may know exactly what you wish to present. State the amount of floor space you desire, and also the minimum amount necessary for you to display your material adequately. Also state if a paper dealing with the material is to be read before a section. The Committee invites the co-operation of physicians in making up the exhibit.

ARTHUR J. BEDELL, M.D., *Chairman,*
Committee on Scientific Work.

OSWEGO COUNTY

The one hundred and tenth semi-annual meeting of the Medical Society of the County of Oswego was held at the City Club, Hotel Pontiac, Oswego, Nov. 24th, 1931, with the President, Dr. G. A. Marsdeen, in the Chair.

A discussion was held on the chiropractic and osteopathic activities in this county, and various complaints by the members against these cults who practice medicine and surgery without knowledge thereof were cited. A committee, with Dr. S. D. Keller of Fulton as Chairman, was formed to interview the Oswego County Assemblyman and the State Senator, and bring before them these complaints, and also to urge them to vote against any bill introduced which would be of benefit to these cults.

On motion it was decided that the Medical Society of the County of Oswego will not adopt a fee schedule formulated by the Committee of Medical Economics of the County of Oswego.

On motion it was decided to hold our meetings quarterly instead of semi-annually.

The following officers were duly elected and committees appointed for the year 1932:

President—Dr. E. A. Galdman, Fulton, N. Y.
Vice-President—Dr. S. M. Burns, Oswego, N. Y.
Treasurer—Dr. J. B. Ringland, Oswego, N. Y.
Secretary—Dr. J. J. Brennan, Oswego, N. Y.

Delegate to the State Society—Dr. G. A. Marsdeen, Oswego, N. Y.

Board of Censors—Dr. A. C. Calisch, Dr. L. F. Hollis, Dr. H. Albertson

Medical Economics Committee—Dr. S. M. Burns and Dr. S. D. Keller

Publicity Committee and Reporter—Dr. J. J. Brennan

Public Health and Relation Committee—Dr. Clifford Hervey, Chairman

Physical Therapy Committee—Dr. H. Wallace, Dr. Reuben LaVine, Dr. J. J. Brennan

On recommendation of the Board of Censors, the following new members were elected to the Society: Dr. Wm. Fivaz, Fulton, N. Y.; Dr. Wm. Birrell, Central Square, N. Y., and Dr. J. F. Burden, Oswego, N. Y.

A very interesting and instructive symposium on gall bladder disease was presented from an internist's viewpoint by Dr. Henry Haft, Syracuse, Asst. Physician to the University and Free Dispensary; the surgeon's viewpoint by Dr. H. D. Mitchell, Rochester, N. Y., Staff Surgeon to the Genesee Hospital; the roentgenologist's viewpoint by Dr. C. F. Potter, Syracuse, N. Y., Roentgenologist to the Crouse Irving Hospital.

J. J. BRENNAN, *Secretary.*

THE DAILY PRESS

REFUGE FOR SHORE BIRDS ON LONG ISLAND

The medical profession includes many nature lovers who hunt with the camera as well as the gun. Long Island doctors are familiar with the snipe, ducks and other migratory birds which visit the bogs and marshes in such numbers that their extermination seems impossible. Moreover, many kinds, such as terns and bitterns, which have been rare for years, are now plentiful because of the protection afforded to them by law, and public sentiment. But the abundance of wild birds is due largely to the position of Long Island at right angles to the line of migration of the birds, so that in the fall the birds find it to be the last resting place before the long flight to the Chesapeake marshes. It is therefore welcome news that a bird refuge will be established almost within sight of Greater New York. The New York *Herald Tribune* of December 14 says:

"The Department of Agriculture has arranged with the Town of Hempstead and the Hempstead Development Commission to lease 2,274 acres between Woodmere and Hewlett, L. I. for a migra-

tory bird refuge and will take over the property soon after January 1. It was announced today by John Miles Flynn, of the Biological Survey, who conducted the negotiations. The rental will be from \$4 to \$6 an acre a year and the lease will be signed for fifteen years.

"Some of the property is under water, some is marsh land and some is higher ground, with abundance of food and nesting room.

"Mr. Flynn pointed out that Long Island was a favorite spot for hunters and that many birds were destroyed there every year, so that when the Department of Agriculture acquired funds recently for ten new refuges in nine states, Long Island was one of the first sites considered.

"The new refuge probably will be populous with ducks, geese, woodcock, snipe and other game birds, Mr. Flynn said, adding that it would be better for future generations to see these birds alive than only in photographs or color plates. With the setting aside of this preserve much of Long Island will be closed to shooting."

FORD'S AID TO UNEMPLOYED

The New York *Times* of December 17 contains a description of Henry Ford's plan to aid the people of Inkster, a village of colored workers who had been employed in the Ford plants, but who have been out of work for six months or more. After a lengthy description of the village now, contrasted with its appearance during prosperous times, the *Times* investigator ascribed the poverty and suffering to lavish expenditures for luxuries at the solicitation of high pressure salesmen.

Hundreds of dollars of debts had been incurred by many of the men—even as high as \$3,800 in one case—and as fast as the men went back to work their pay was garnished, until not a sufficient amount was left to feed and clothe their families. The women and children suffered as much as ever. Also in some cases, the feeling that hard times were over expressed itself in folly.

"Investigators found a new washing machine in a home where there was no food. They learned that the housewife had purchased it on easy payments because the company selling it offered a turkey free with each machine."

The *Times* then described the remedies instituted by Mr. Ford.

"The men were taken out of the \$6 a day group and work was given to them at 12½ cents an hour, \$1 a day being about what was needed actually to feed these families.

"Meantime, the Ford Motor Company 'O. K.' d' all the outstanding accounts—electric, gas, installment payments and real estate contracts.

"It has also now established a temporary commissary where food may be purchased at practically wholesale prices. A hot vegetable kitchen has been opened where on Nov. 9 1,700 received supplies and 647 were cared for on Dec. 14.

"The wives of the men employed by the Ford Motor Company volunteer their services in the kitchen, a new crew being used every day so that they are actively contributing and are happy.

"A shoe cobbling department reconditions shoes for 65 cents a pair. Clothing has been furnished in amounts ranging from \$25 to \$40 a person.

"For these supplies the Ford Motor Company accepts 'I. O. U.'s' from such employees. Just how much each man actually earns depends upon

himself—his demonstration of willingness to work and sobriety of judgment.

"Nothing is being given to any one free, but the entire community is being guided out of inextricable difficulties to the status of contributing citizens.

"This is not competition with the regular merchants of Detroit, because these victims of the depression would have no individual purchasing power.

"Henry Ford believes in only three kinds of charity—for hopeless cripples, the aged, and chil-

dren. For the able-bodied he believes the greatest thing that can be offered is opportunity.

"So, instead of assuming as a charitable burden a rehabilitation of these people so long out of employment, a rehabilitation which, so easily acquired, would doubtless only be temporary, he is attempting to make them face soberly the question of their own reinstatement as earners and providers, to impress upon them the facts that the grasshopper is not a desirable economic model, and that high wages may be followed by unemployment for which they should provide."

EXPOSURE OF PAID TESTIMONIALS

The New York *Herald Tribune* of December 21 contains the following item on giving publicity of the pay received for testimonials:

"WASHINGTON, Dec. 20.—Following an investigation of the facts concerning testimonials obtained for advertising purposes from four women of international prominence, the Federal Trade Commission announced today that it has ordered no further use of such indorsements unless the advertisements disclose the payments made for them.

"The order is issued against a corporation of New York, manufacturers of toilet articles, which was found to have paid substantial sums for the testimonials in behalf of a manicuring preparation.

"This is the first step in a move by the commission to enforce full publicity for methods used in obtaining advertising testimonials from

prominent persons. That it will be combated was indicated by word from officials of the corporation involved, who plan an appeal to the United States Circuit Court of Appeals."

The newspaper prints the amount received by five prominent women for testimonials varying from \$1,000 to \$150, and continues:

"These advertisements were published at various times from 1928 to 1930. As an illustration of the procedure there is quoted a letter from an actress, promising to permit the use of her name and photograph with a statement to be submitted to her and approved.

"She authorized the use of a statement prepared to advertise the product in question, but also referring to herself as 'the best loved actress on the American stage.'

"'Everything must flatter us to our finger tips,' she allowed herself to be quoted as saying in indorsing the finger nail polish."

PHYSICAL DEFECTS OF CHILDREN

The New York *Herald Tribune* of December 9 has the following editorial on defects of children. After quoting statistics of the millions of children who are undernourished, and have damaged hearts and other defects, the writer continues his editorial:

"To list such blemishes is not, of course, the whole of the story. Were this age compared with almost any other in human history it is certain that the record would look less black. Perfect childhood has never been universal, nor is it likely that mankind does worse with its children today and in America than before or elsewhere, except perhaps in a few small and highly favored communities like Switzerland. This does not mean that nothing need be done about the defects which Dr. Averill arraigns, but what needs to be done, fearless consideration of biological facts suggests, is something much more drastic and much less easy than merely to relieve present misfortunes of

children who are underfed or deaf or mentally defective.

"The reason why so many children now suffer from personal defects is not that the human species is deteriorating, although that may be true. Nor is it that civilization is less careful or competent. It is merely that incompetents, infant or adult, now are more likely than formerly to be kept alive. It is useless to blink the fact that rigid elimination of the unfit, just or unjust, is Nature's method, with which man has interfered, and perhaps has interfered at serious peril—none of which need be taken to urge return to conditions of savagery in which all unfit persons are killed or allowed to die as Nature takes her ruthless course! The point is merely that solutions for these matters of inexorable biology are less simple than even Dr. Averill seems to believe, although arguments like this are useful to keep us from forgetting what some day we must solve or die."

BOOK REVIEWS

THE DOCTOR AND HIS INVESTMENTS Financial Policy and Technique for the Physician By MERRYLE STANLEY RUYSEYER, B Lit, M A 12mo of 330 pages Philadelphia, P Blakiston's Son & Co, Inc., 1931 Cloth, \$2.50

The writer is a financial editor and has had considerable experience. While he considers the Doctor's investment problems different from those of other individuals, his specialization in advising the buying of stocks and bonds is stressed a little too much but always with caution. His knowledge of the financial problems of a physician is very acute and his advice as to other investments is intelligent.

It is a book that every physician should read. Chapter 10 (Promises and Woes of Speculation), referring to buying stocks on margin, should be forever before the reader's eyes, in which the author says, "The Medical man with a Surgeon's knife in one hand and the Ticker Tape in the other is a sorry spectacle."

His attitude toward Life Insurance and Real Estate should be carefully read and we believe the sooner the young practitioner maps out his course for financial ease along the lines the author suggests and makes a detour through Wall Street and the stock question, the sooner an income will be assured him and the safer his dependents will become. M J DATTELBAUM

TREATMENT OF INJURY BY THE GENERAL PRACTITIONER By CLAY RAY MURRAY, M D, F A C S Two volumes 12mo of 412 pages, illustrated New York and London, Harper & Brothers, 1931 Cloth, \$5.00 (Harper's Medical Monographs)

These two volumes represent part of Harper's Medical Monographs, and just why this particular monograph should have been divided into two volumes is difficult to understand.

However, the contents represent a brief, practical and concise treatise on this subject. There are 404 pages with 196 drawings by the author. These black and white drawings are excellent illustrations of some of the methods of treatment and conditions encountered by the general practitioner.

Chapter one in volume one contains much "food for thought", particularly for those who have to deal with compensation cases. Patient psychology and surgical shock are discussed briefly, but in a very practical manner in this chapter.

The modern and accepted treatment for fractures is very clearly illustrated and described.

These two volumes would be an excellent asset to the library of the general practitioner.

HERBERT T WILKIF

RECLAIMING THE DRINKER. By CHARLES B TOWNS 12mo of 77 pages New York. Barnes & Company [c 1931] Cloth, \$1.00

Reclaiming the Drinker' is a frank discussion of alcohol and its effects. Mr. Towns' work with alcoholics and other drug habits over a period of more than 30 years has given him a clear understanding of these maladies and their control. He handles his subject in a satisfactory and authoritative manner. Simply written yet presenting a mass of information in an easily read and understood form the book is worthy of recommendation to the man who drinks as well as to the society of which he is a member. FREDRIC DAMRAU

SURGERY, ITS PRINCIPLES AND PRACTICE for Students and Practitioners By ASTLEY PASTON COOPER ASHURST, A B, M D Fourth edition Octavo of 1189 pages, illustrated Philadelphia, Lea & Febiger 1931 Cloth, \$10.00

This single volume of surgery, comprising 1189 pages and 1063 plates and illustrations appears as the fourth edition of the work. It is essentially a text book for students and is presented as a means of supplying a source of information to be used or to be supplemented by more complete works and by further practice as the requirements of the student or practitioner demand.

There are twenty nine chapters, the first nine deal with general surgery, the next seven chapters discuss systemic surgery, such as, surgery of the blood vessels, skin, burst, muscles, tendons, nerves, fractures, injuries of joints, diseases of bone and joints and orthopedic surgery. The remaining thirteen chapters deal with regional surgery, including that of the head, spine, nose, neck, chest, hernia, abdomen, the genito-urinary system of both male and female.

This book has been brought completely up to date. Many of the sections have been entirely rewritten and all of them have undergone extensive revision.

Among the new matter introduced might be mentioned giant cell tumors, rectal and spinal anesthesia, thrombo phlebitis obliterans. The injection treatment of varicose veins, the electro-surgical apparatus, hyperthyroidism, gastric ulcers, and tumors of the sympathetic nervous system are also introduced.

The specialties of the eye, the ear, the nose, and the throat are quite properly not included. The surgery of the genito-urinary tract and of gynecology and orthopedics are discussed only so far as they come within the province of the general surgeon.

The reviewer feels that because of the complete yet concise, method of presentation, and because of its easy reading, this book is to be highly recommended for medical students and as a text book for the general practitioner and surgeon.

MERRILL N FOOTE.

PATHOLOGY, BACTERIOLOGY AND APPLIED IMMUNOLOGY FOR NURSES By ROBERT A KILDUFFE A B A M Octavo of 324 pages, illustrated Milwaukee The Bruce Publishing Company, [c 1931] Cloth, \$2.50

This volume makes a difficult task simple. Those who teach nurses will best appreciate the advantage of treating the interlocking subjects of bacteriology, applied immunology and pathology in one course. Besides being of value as a text for lecturers this book can be recommended as a reference book for post graduate students of nursing.

SILK H POLAYES

BREAST FEEDING By MARGARET ENSLIF M B Ch B 12mo of 142 pages, illustrated New York and London Oxford University Press 1931 Cloth \$2.00 (Oxford Medical Publications)

A very commonsense little volume, which, in a not too comprehensive way, establishes in one's mind how breast feeding may be handled successfully. Chapter II especially deserves mention and physicians who do obstetrical work should study it. Various types of breasts and nipples are described and illustrated and ways and means of preparing each for successful nursing are given in ample thought. THIRMAN B GILMAN

OUR NEIGHBORS

HEALTH ADMINISTRATION IN MAINE

The appointment of a Special Health Commission by Governor Roosevelt of New York State on May first, 1930, was paralleled by the action of Governor William Tudor Gardiner of the State of Maine in appointing a Commission that should suggest changes in the form of administration in all branches of the State Government, including the Department of Health. A brief notice of a public referendum on a Code Bill suggested by the Commission was printed in this *Journal* of December 1, 1931, page 1493. The *Maine Medical Journal* of November states that the referendum was carried by a large majority, at the general election on November 9, and that the reorganization is now a fact. Dr. Philip W. Davis, Secretary of the Maine Medical Association, expressed his opinion regarding the new Code as follows:

"I feel that the passage of the Code Bill and its confirmation by the people of Maine November 9th was a real step forward. This bill created a Commissioner of Health and Welfare, a new office. He is to have general supervision of all Health and Welfare activities including State Institutions.

"The bill as passed does away with twenty-eight departments, bureaus and agencies and replaces them with four departments. Of course no system is 100% and much will depend upon the quality of the man appointed Commissioner of Health and Welfare. The Governor has not yet made this appointment but I have every reason to suppose that he will be a doctor who has had wide experience in institutional management."

Dr. Davis also sent some descriptive pamphlets regarding the new Code, from which the story of its adoption was obtained.

An impartial survey of the administration of the governmental organization of the State of Maine was made by a legislative committee, but when Governor Gardiner was inaugurated in 1929, he said: "All the State's activities should be under constant survey for any possible consolidation that might make for efficiency and economy," and he referred to the fact that the business of the State was administered by over forty governmental agencies. Later the Governor said:

"I had neither the time nor the technical ability to make a complete survey, but learned of the work of the National Institute of Public Administration which is qualified for such a task to a degree which is generally conceded to be un-

equalled. Their services cost money, the Legislature was not in session, and the sum seemed too large to draw from the contingent fund. I therefore solicited and received an unrestricted gift of \$20,000 from the Spelman Fund, the trustees of which are interested in the technical aspects of government. The staff of the Institute rendered a most comprehensive report on all the activities of the State, which was printed in a pamphlet of 214 pages and distributed as widely as possible."

When the report was received, it was referred by the Governor to a committee of seventeen persons whom he appointed to study the report and to suggest the proper action to be taken. The committee conducted public meetings in six sections of the State, and consulted the people on the reorganization to be suggested. On January 20, 1931, the Committee reported:

"At the first meeting of our committee we discussed the scope of legislation which might be introduced pursuant to the recommendations of the Survey. After reaching our own conclusions, we entrusted the task of drafting an administrative code along the lines agreed upon, to Mr. A. E. Buck of the Institute staff, whose qualifications and experience in this type of work are outstanding. Later, the committee, with Mr. Buck, went over the Code, discussing its terms section by section. The revised bill, entitled the 'State Administrative Reorganization Code' embodies all our suggestions.

"We have recommended a thorough-going financial reorganization which we believe will merit the approval of public finance experts. Through the Department of Finance, if established substantially as recommended, we believe real economies can be effected. Another important change which we propose in departmental organization is the association of health work, social welfare work, and institutional administration in three coordinated bureaus in a Department of Health and Welfare. This presents an opportunity not only for preventing further increase in our expenditures for those purposes, but also for going to the very root of the purpose behind all those activities, which is the conservation of our human resources through reduction in human misery, poverty, and disease."

The bill suggested by the Committee was introduced in the Legislature on January 21, 1931, and was passed on April 2; but a petition was filed that it be submitted to a referendum vote

(Continued on page 42—Adv. xviii)

"If one wishes to fortify cod liver oil, it is far more reasonable and efficacious to increase its potency by adding a small amount of viosterol, which is a specific in the prevention and cure of rickets, as it brings about calcification not only of the bone but of the proliferating cartilage as well." (Hess, Alfred F., Am. J. Dis. Child. 41:1081; May, 1931.)

MEAD'S 10 D Cod Liver Oil with Viosterol is the choice of many discriminating physicians because it represents the long pioneer experience of Mead Johnson & Company in the fields of *both* cod liver oil *and* viosterol.

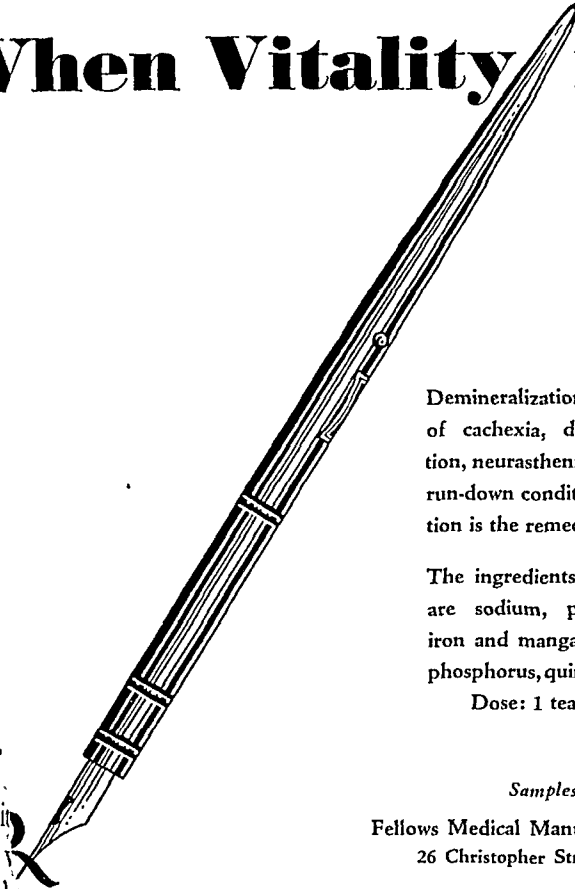

Mead's 10 D Cod Liver Oil is the only brand that combines *all* of the following features:

1. Council-accepted.
2. Made of Newfoundland oil (reported by Profs. Drummond and Hilditch to be higher in vitamins A and D than Norwegian, Scottish and Icelandic oils).
3. Supplied in brown bottles and light-proof cartons (these authorities have also demonstrated that vitamin A deteriorates rapidly when stored in white bottles).

In addition, Mead's 10 D Cod Liver Oil is ethically marketed without public advertising or dosage directions or clinical information. With Mead's,—*you* control the progress of the case.

Mead's 10 D Cod Liver Oil is therefore worthy of your personal and unfailing specification. This product is supplied in 3-oz. and 16-oz. brown bottles and light-proof cartons. The patient appreciates the economy of the large size.

When Vitality is Low

Demineralization causes many cases of cachexia, debility, undernutrition, neurasthenia, anemia and other run-down conditions. Remineralization is the remedy.

The ingredients of Fellows' Syrup are sodium, potassium, calcium, iron and manganese, together with phosphorus, quinine and strychnine.

Dose: 1 teaspoonful t. i. d.

Mead Johnson & Co.

(Continued from page 42—Adv. xviii)

The bill also creates an advisory council of six members, whose duties are defined as follows:

"1. To make such investigation of the social problems of the State, with the aid of the departmental staff, as the commissioner of health and welfare may request;

"2. To advise the commissioner of health and welfare with reference to the policy of the department of health and welfare and other matters falling within the jurisdiction of said department.

"3. To recommend to the commissioner of health and welfare the enactment of such laws as may be deemed necessary relative to the activities of the department of health and welfare.

"4. To make such rules and regulations as may be deemed necessary to carry out the intent of the public health and welfare laws of the State."

The sections on the Departments of Fisheries and of Education are extremely brief and do not change the present system to any great extent.

Article six creates a fifth Department,—that of Audit.

The law closes with a list of twenty-eight agencies which are abolished.

The editor of the *Journal* believes that the new law will help to make Maine a good place in which to live and practice for he says editorially:

"Young medical men locating in Maine in the next decade should prosper. More than one-fourth of her present practitioners have passed the 60-year milestone. Maine should continue to afford a profitable field for the practice of medicine. An awakened profession cooperating with a sympathetic government and intelligent public seem to be securing results in establishing a dignified control of medical affairs. The provisions of the Code should now make it possible for the profession to exercise with authority in a recognized advisory capacity a stronger influence for good in matters of health and welfare. Our continued interest and insistence will maintain medical men of character as well as brains in positions of trust. Such men will now serve, assured of our support."

HOUSE OF DELEGATES OF KENTUCKY

The December number of the *Kentucky Medical Journal* contains the minutes of the annual meeting of the Kentucky State Medical Association held September 7-10, 1931, at the University of Kentucky, Lexington. An editorial states that the *Journal* contains a verbatim report of all that was spoken or read in the House of Dele-

Colloidal IRON in ANEMIAS

Prescribed in
8 oz. bottles

Dose,
dr. i. t.i.d. p.c.

IDOZAN is a stable colloidal iron solution, NEUTRAL, and contains 5% of iron.

Colloidal iron therapy represents a significant advance over the old iron preparations.

IDOZAN is an active iron preparation which will produce a definite rise in the hemoglobin in cases of simple anemia, chlorosis, secondary anemia and post partum hemorrhage.

IDOZAN makes "new blood," better blood; thus acting as a dependable "iron tonic."

gates, and the statement is probably true, for the minutes fill forty-eight pages.

Twenty-six reference committees were appointed, as follows:

Credentials	Heart
Scientific Work	Cancer
Medico-Legal	Health Problems
Crippled Children	County Hospitals
Journal	Ethics
Legislation	Auditing
Miscellaneous	Resolutions
Publicity	Students' Loans
Exhibits	Graduate Courses
Medical Education	Woman's Auxiliary
Health Examinations	Council
Hospitals	Veterans
Workmen's Compensation	Goiter

There is scarcely a mention of any action taken by a reference committee.

Division of Fees: The Secretary's report mentioned the division of fees as the most serious evil threatening the medical profession. He calls attention to the following provision of Chapter One of the By-Laws of the State Association:

"No physician may become a member of any county society unless he signs and keeps inviolate the following pledge:

"I hereby promise upon my honor as a gentleman that I will not as long as I am a member of the Kentucky State Medical Association practice division of fees in any form, neither by collecting fees from others referring patients to me nor by permitting them to collect any fees for me; nor will I make joint fees with physicians or surgeons referring patients to me for operation or consultation; neither will I in any way, directly or indirectly, compensate anyone referring patients to me, nor will I utilize any man as an assistant as a subterfuge for this purpose."

Division of Fees: The Secretary also calls attention to a State law of 1916 on the division of fees, as follows:

"Be it enacted by the General Assembly of the Commonwealth of Kentucky:

"I. That hereafter any physician, surgeon or any other person, who carries, sends, or is in any manner instrumental or aids and abets in causing a patient to go to another physician or surgeon for surgical operation or advice as to or the treatment of any physical or mental disease, injury or ailment, and receives therefor from such other physician or surgeon any money, gift, or other thing of value for having furnished such patient or who has any agreement or understanding with such physician or surgeon to receive therefor any money, gift, or other thing of value whatsoever from such physician or surgeon, without the knowledge and consent of the patient pre-

viously obtained, shall be guilty of selling the patient within the meaning of this Act."

The entire law fills a column and a half, and provides for a fine of \$100 for each offense for both the buyer and the seller of patients.

The reports of the councilors of the eleven districts fill over three pages; and the reports of delegates from twenty-one county societies fill six pages. They make interesting reading. The delegate from Gerrard County, for example, reported:

"We have six physicians in Gerrard County, all of whom are members of our society. We haven't had a meeting for so long that I really don't know when we did have one."

The Bourbon County delegate said:

"We have twenty-five doctors in the county: twenty-one are regular practitioners; two homeopaths, two cultists. We have nineteen members paid out of the twenty-one. The other two are rather hard to get, some way or other. We are going to slide under them and drag them in sometime."

Crippled Children: The Committee on Crippled Children reported on the work of the Kentucky Crippled Children Commission for the year ending September 1, 1931, stating that sixteen free diagnostic clinics had been held, and that the conditions treated and number of cases were as follows:

"Infantile paralysis	357
"Spastic paralysis	100
"Other paralysis	65
"Congenital deformities	213
"Bone tuberculosis	58
"Injuries	80
"Osteomyelitis	56
"Scoliosis	19
"Arthritis	35
"Rickets	34
"Non-orthopedic and mental	97
"Miscellaneous	85

"Total 1,199"

"I do not believe there has been a finer piece of medical or medico-sociological work done anywhere than has been done by the Kentucky Crippled Children's Commission. It has been done largely under the guidance of this Association and particularly of those of its members who limit their practice to orthopedic surgery. It is being done without an adverse criticism by anybody."

The chairman asked the question:

"What other form of organization can we make that would enable us to take care of those

(Continued on page 49—Adv. xxv)

(Continued from page 48—*Idt. rrr*)

very much larger groups, because the crippled children's group consists of some 6,000 to 12,000 in Kentucky? How far do we propose to go in the development of other commissions for the treatment and alleviation of the conditions in the larger groups that compose the disabled, that are remediable to a considerable degree?"

One doctor commented

"If this thing is carried to its logical conclusion, it seems to me we are right at State medicine. If we are going to have commissions that are going to scour the State with enthusiasm which a well organized commission exhibits and with the efficiency that is developed in these organizations, we are going to have organizations which will gather not only all those who are totally unable to pay, but those for whom it is considerable sacrifice to pay, and treat them gratuitously."

Answer was made.

"As we use the term 'crippled children,' it is for the orthopedic surgeon. I think there we are justified in allowing a commission of this kind to exist, and I do not think that the average physician throughout our State is qualified or prepared to treat the case when it is sent back. I have

seen some very bad failures following the turning over of those patients to physicians. They do not have the qualifications or the equipment necessary to handle those orthopedic cases."

A resolution was passed to sponsor a legislative bill to raise the limit of medical fees in a compensation from the present \$200 to \$700. Medical ethics collection agencies, and undergraduate education were discussed at length.

Law Enforcement. The report of the Council has the following reference to law enforcement.

"For the past seven years the Association has cooperated with the State Board of Health in the enforcement of medical practice and other health laws. The House last year authorized an expenditure not to exceed \$1,200 for this purpose. Fortunately we were called on to expend only \$300 of this amount. The Council recommends the appropriation of not to exceed \$1,200 for the same purpose for the next year."

"It will be impossible to improve conditions in these sections until public opinion has been educated as to the importance of the selection of competent officials. This year, again, our attorneys have assisted in the preparation of more than 143 cases and they have been effectively

(Continued on page 50—*Adv. rrr*)

LIQUID PEPTONOIDS WITH CREOSOTE

COMBINES the active and known therapeutic qualities of creosote and guaiacol with the nutritive properties of Liquid Peptonoids and is accordingly a thoroughly dependable product of definite quantities and recognized qualities as shown by the formula:

Each tablespoonful represents

ALCOHOL (By Volume)	12%
PURE BEECHWOOD CREOSOTE	2 min
GUAIACOL	1 min
PROTEINS (Peptones and Propeptones)	5.25%
LACTOSE AND DEXTROSE	11.3%
CANE SUGAR	2.5%
MINERAL CONSTITUENTS (Ash)	0.95%

It acts as a bronchial sedative and expectorant, exhibiting a peculiar ability to relieve Bronchitis—acute or chronic. It checks as well a persistent winter cough and without harsh or untoward effect. It is agreeable to the palate and acceptable to the stomach—with merit as an intestinal antiseptic. Supplied in 12 oz. bottles.

aided by the commonwealth and county attorneys in many sections of the State.

"The careful management of the Medico-Legal Committee has kept the cost of attorney's fees at practically the same figure as the preceding year, \$1.125 for 1931 as against \$1.025 for the preceding year. Court costs and expenses of this committee were \$190.25 as against \$154.85 for the preceding year.

"We regret to report that there is no decrease in the number of such unjust blackmail suits against reputable members of the profession."

The House of Delegates voted to recommend the establishment of State institute for the study of all phases of the problem of the detection of criminals, and for making fingerprints, chemical analysis, the examination of bullets, and all other modern investigations for the detection of crime and criminals.

The greater part of the minutes of the House of Delegates consist of reports of the committee... and of theoretical discussions of the reports.

DUES IN PENNSYLVANIA

The November number of the *Pennsylvania Medical Journal* contains the minutes of the annual meeting of the House of Delegates held October 5, 1931, in Scranton. The subject of reducing the annual dues was brought up by representatives of the Philadelphia County Society in the following resolution:—

"Whereas, This Country is experiencing the greatest financial stress of its history, and

"Whereas, This national condition is reflected on all medical organizations, especially the county medical societies of this State, and

"Whereas, We in Philadelphia are being particularly stressed as our County Society has formulated certain schedules in the way of scientific education for both physicians and laymen, publicity, welfare, etc., which naturally has put a constant drain on our exchequer, and

"Whereas, These premises through laborious work and expenditure of much money have developed into an almost well-founded reality, and, it would be nigh onto a tragedy if these activities were inhibited at this time, and

"Whereas, Other conditions are arising in the social and economic side of medicine, insurance companies, compensation boards, panel systems, health insurance, foundations established to analyze the high cost of medicine, and too numerous allied societies cooperating to dictate the welfare and existence of the physician, and

"Whereas, So it seems to this Committee that

X-Ray Proves the Superiority of this Colloidal Bismuth Solution

Bi-Na-Gluconate
Completely Absorbed
48 Hours After
Injection and slowly
eliminated in Syphilis

THE therapeutic value of bismuth in the treatment of syphilis is dependent upon the absorability of the solution and its slow elimination, rather than on the amount injected. Maximum benefits are obtained only when the absorption is rapid and complete, coupled with the proper storage of the bismuth.

Some of the points of superiority of **Bi-Na-Gluconate**:

a. **Bi-Na-Gluconate** being both water and tissue soluble and in *True Colloidal State*, is quickly absorbed and assimilated and slowly eliminated. Thus its full therapeutic availability is assured.

b. **Bi-Na-Gluconate** injections are painless when given $1\frac{1}{2}$ to 2 inches deep intragluteally.

c. **Bi-Na-Gluconate** solution is perfectly stable, not affected by heat or light.

d. A smaller dose of **Bi-Na-Gluconate**, which is a true colloidal solution of bismuth, is more effective than a larger dose of a non-colloidal or a protective colloidal solution of bismuth, because of its more rapid absorability and complete utilization.

e. **Bi-Na-Gluconate** under the ultramicroscope is more energetic with a finer colloidal dispersion than other aqueous bismuth solutions similarly examined.

f. The toxic dose of **Bi-Na-Gluconate** is 125 to 150 times the therapeutic dose. No local induration or systemic reactions are produced.

Bi-Na-Gluconate is supplied in *Hyposols* (ampuls)—12, 25 and 100 in a package.

Immediately after injections.

Roentgenological examination shows complete absorption of **Bi-Na-Gluconate** in 48 hours.

48 hours after injections.

A brochure is available describing **Bi-Na-Gluconate** and its role in the treatment of Syphilis. A copy will be sent to physicians on request.

Bi-Na-Gluconate

this is not the time to put away great reserves, but to spend what monies we have to combat the influx of these various elements, and

"Whereas, The State Medical Society is now the proud possessor of a reserve fund of some \$263,000.00, which I take has been accumulated for a rainy day; therefore, be it

"Resolved, That this Committee feels that the rainy day is here and we therefore resolve that the State Medical Society reduce for one year the per capita tax payable to the State Society from \$7.50 to \$5.00."

Dr. G. C. Yeager gave the following arguments in favor of a resolution to reduce the annual state dues from \$7.50 as at present to \$5.00:—

"We know that many of our members are not here because of their present financial condition. The State Society, we feel, can get along very well on \$5.00 this next year, and \$2.50 will look as large as this room to the Philadelphia County Society. We try to lead you all in scientific training and in education. We conduct many clinics, and seminars, do broadcasting and all this runs into big money. We have an executive secretary and two stenographers who are busy all day with that kind of work. We have a terrific

handicap because we are the largest society in the State. We want to lead in education and in publicity, which costs us a great deal, and we feel that if we are to take care of these malpractice suits as the first line of defense we will need a little fund to meet it. If these people find out that these suits are never won, that they are always defeated, they will stop. We want to keep on with our publicity. We feel that with the splendid reserve fund in the State Society, with the handsome home in Harrisburg, which I understand is all paid for, we feel that it would be good policy to adopt this plan for the coming year."

Dr. S. A. Brumm spoke as follows:—

"Our members are dropping away from us because of their financial condition. At present we have twenty members whom we are carrying to keep them in good standing in the State Society. We have twenty more who have begged us not to take them off the roll because they are unable at present to meet their obligations, but who hope to be able later to pay their dues."

Arguments against the reduction of dues were given as follows:

"No other society in the State, so far as I know, has asked for a reduction. Every article of our expense is increasing. I spoke of the

great increase in the Medical Defense cases. We are establishing a bad precedent if we approve this reduction now. In 1928 when we asked for an increase from \$5.00 to \$7.50, we had a per-capita expense of \$5.34. At the present time it is \$6.54. Our defense case fees are increasing, along with everything else. It is your money, you are as much interested as the Board of Trustees. I am sure I express the sentiments of the Board of Trustees and I am positive of the president and retiring president in saying that this reduction should not be made.

Our medical defense cases have increased three hundred per cent in number over the average in the last six years. These demands have to be met and approved applicants defended. Lawyers' fees have gone up in comparison, as has already been said. Of the medical defense cases which we have had recently, two thirds have come from Philadelphia County alone.

The motion was lost with a vote of 40 for reducing the dues, and 41 against the reduction.

It would seem that the Pennsylvania society acted wisely in not reducing its annual dues for a society cannot work without money.

IOWA UNIVERSITY HEALTH SERVICE

The responsibility of college authorities for the health of their students is being recognized to an increasing degree. (For a survey of health service in New York Colleges see this Journal, November 1, 1930 page 1283.) The University of Iowa organized a service in 1930 and the results of its first year of operation are set forth in the Journal of the Iowa State Medical Society for November, 1931, page 636 as follows:

Nearly ten thousand young men and women from all parts of Iowa are enrolled each year in the State University. It is of statewide importance that strict supervision be kept over the health conditions under which these students live.

"The University has organized a Department of Health, conducted by Dr. Milford F. Barnes, head of the Department of Hygiene and Preventive Medicine, and Dr. A. V. Hardy, Associate Professor in the same department.

"It operates through five divisions. The Divisions of Communicable Disease, Life Extension, Student Outpatient, Inspection and Records. A chief heads each division and is aided by a staff of assistants drawn from various faculties.

"All cases of diphtheria, tuberculosis and communicable maladies that come to the University hospitals are carefully investigated, both as to the source of the illness and to the possible exposure of other people.

"In September of 1930, 432 students were given complete physical examinations by the Life Extension Division of the University health department. In October, 626 students were examined, and through the rest of the year up to May more than 500 additional examinations were made.

"If maladies are found, the person examined is advised, but not obliged, to take remedial measures. Students are privileged to seek medical service of private physicians or at the University Hospital. If it is necessary to go to the University Hospital, minimum rates are charged.

"Freshmen are all required to take the physical examinations and any upper classman may avail himself of this opportunity. It is interesting to observe that each year a larger number of them are realizing the advantages of such an offer.

"The Life Extension Division requires every food handler in the dining rooms of the University, as well as the fraternity and sorority dining rooms, to have physical examinations. In addition, this requirement is extended to include nurses and all employees of the University Hospitals. To be on the positive side, all of the workers who are carriers of typhoid, diphtheria, venereal diseases, or tuberculosis are barred from service in the hospitals or dining rooms. Moreover, all employees must agree to notify the Life Extension Division if they come in contact with or are affected by any communicable disease. Under these conditions a permit to work is granted which is revocable if the employee does not live up to his agreement.

"The Student Outpatient Division, a unique feature of the University Department of Health, employs three full-time physicians and a nurse and is housed in ten complete outfitted rooms. It can readily be seen that the best possible care can be given to any students who are ill and desire medical attention of any sort. Nominal charges are made for office and room calls. Over 6,500 patients were treated by the division during the last school year.

"The benefits of remedial and preventive work of this nature cannot be stated definitely. However, it is interesting to note that the number of services rendered by the Department of Health for the different divisions, from September 1, 1930, to May 31, 1931, ranged as follows: Communicable Diseases, 60 (cases investigated); Life Extension, 8,533; Student Outpatient, 6,871; Inspection, 3,103. These statistics furnish some insight as to the service rendered.

(Continued on page 55—Adv. xxxi)

(Continued from page 54—Adv. cont.)

"The fact that there is a department of this kind functioning in a highly efficient manner should be reassuring to physicians and citizens of all parts of the state that the State University is not only a safe place for students, but also that students returning from the University will not disseminate contagious diseases in their respective communities."

STATE JOURNAL OF ALABAMA

The Journal of the Medical Association of the State of Alabama was started in July, 1931, as the organ of both the State Association and the State Board of Health. The public health department occupies the latter part of the Journal and is conducted by officials connected with the State Board of Health. That department in the November number contains articles contributed by the heads of the Bureau of administration, laboratories, vital statistics, preventable diseases, inspection, child hygiene and public health nursing, engineering.

The articles are practical and of informative value to general practitioners of medicine.

Referring to aid from the U. S. Government and other outside agencies, the Journal said:

"It was during this growing, formative stage that the Rockefeller Foundation and the United States Public Health Service, appreciating the soundness and strength of our public health organization, donated so liberally, both in money and in personnel, to the rapid building up of what they then considered and what the world now concedes, is one of the finest pieces of health machinery in existence. So liberal were these agencies to Alabama that her health department was frequently referred to as 'The Branch Office of the United States Public Health Service and the Rockefeller Foundation'.

"This fact, however, must be borne in mind. These aids were but temporary and those activities into which these extraneous monies were poured if continued, had to be paid for at the State's expense. To illustrate beginning in 1922, through the Sheppard Lowner Act, Alabama received annually from federal sources \$25,836 to be expended for rural health nursing. This activity proved of such great worth and so necessary that upon the discontinuance of this federal subsidy in 1929 this financial burden became the responsibility of this department. In the eyes of these various agencies, whose efforts are aimed primarily at setting health departments on their own feet, Alabama is viewed as, long since having passed the crawling stage in public health work.

securing speakers. Dr. Flippin will doubtless be glad to assist you in selecting a subject and will also help you in securing clinicians or speakers.

"The Department of Clinical Education will hold the regular meeting in Richmond in December, and at that time it will probably be decided whether the committee on Postnatal and Prenatal clinics will undertake to begin their work during the current year. This is a sub-committee of the Department of Clinical Education. It is composed of two members from each of the State Medical Schools, two from the Society at large and two, added at the request of a special committee meeting in Roanoke, who are country doctors. The whole purpose of these clinics will be to benefit and educate the physicians through post-graduate training.

"It is contemplated that an able whole-time clinician in obstetrics and gynecology shall conduct clinics in designated centers for groups of physicians, and at times to meet physicians in their offices to assist them, but only at their request. The details of the plan will be published later. It is our sincere desire in attempting to introduce this plan of education to place our profession in the forefront of preventive medicine. We hope to lower the mortality rate of mothers and the newborn to such an extent, and to so impress the public with the efficiency and skill of our physicians, both town and country, that no woman will be satisfied to pass through the ordeal of childbirth without the supervision and care of a competent physician."

COUNTY HEALTH OFFICERS IN WYOMING

The Wyoming section of the November issue of *Colorado Medicine* discusses the public health administration of the State and describes some conditions which are not evident in those States which, like New York, have an effective civil service system. Two features of the Wyoming administration are noteworthy:

1. The violation of the principle of house rule in the appointment of county health officers by the State Board of Health.
2. The assumption of the power of appointing the county health officers by the governor.

A hopeful symptom is the awakening of the physicians to the necessity of taking an active part in both making and administering the public health laws. The article says:

"Some constructive plan should be developed in Wyoming to unite more closely the State Board of Health and all the physicians of the state. At present the State Board of

SCHOOL CHILDREN'S

appetites ARE
fickle

...OFTEN DUE, HOWEVER,
TO TASTELESS OR
UNINVITING DIET

Those in charge of school lunches are often confronted with the problem of getting children to eat what is good for them.

The lack of taste-appeal in the food served is often the reason that food is rejected or "picked at." Cooked tomatoes may be too tart, the stewed fruit insipid, the spinach and the carrots bland.

By flavoring or seasoning these essential foods with sugar they will be much improved in flavor. A dash of sugar to a pinch of salt is a good rule to follow in seasoning string beans, carrots, peas, tomatoes, soups and meat and vegetable stews. Fresh and cooked fruits should be sweetened to taste.

Doctors and diet authorities approve this use of sugar because it makes those foods which are carriers of vitamins, minerals and roughage, more enjoyable to the child. Flavor and season with sugar. The Sugar Institute, 129 Front Street, New York City.

★ "Flavor and season with Sugar" ★

(Continued from page 57—Adv. xxxiii)

Health consists of a Secretary, who is a physician who gives all of his time to the work of the Board, with a small office force of clerks and stenographers. The Board is made up of the Secretary and three regular physicians and one osteopath. The professional standing of the Secretary and the rest of the Board is a fair average of a cross section of the physicians of the state—no better and no worse than the rest of us.

"The governor makes the appointments of this Board and we have no quarrel with him for his designations. The law does, however, vest with the Board the appointment of the county health officers. This right was taken away by the late Governor Emerson who selected the present county health officers and at his wish the list thus prepared was acted upon by the Board, and by rubber stamp methods appointed. That such county health officers thus become political appointments is self-evident.

"Three questions naturally arise. First: Is this the way to secure the best men to fill the office of County Health Officer? Second: Does such a system develop to the fullest extent the State Board of Health? Third: Can it be improved upon?

"At present there seems to be lacking a close contact between the board, the County Health Officer, and the Medical Profession. Something is wrong when such a condition exists. Some of it is the fault of the State Medical Society. Some of it is the fault of the State Board of Health, and some of it rests with all the doctors of the state of Wyoming.

"We feel the Board should present to the State Society at the next annual meeting in Rock Springs some definite plan for the future and at that meeting have a free discussion by the State Society of any plans for closer union and co-operation. The officers of the State Society, therefore, invite the Board of Health to present such plans at our next meeting and assure them time for such discussion."

ANNUAL REGISTRATION IN TEXAS

The annual registration law, which takes effect on January 1, 1932, is discussed editorially in the December number of the *Texas State Journal of Medicine*, as follows:

"The dues of the State Medical Association have been reduced in the amount of the fee, namely, \$2.00. Members of the State Medical Association do not lose anything in the transaction. On the contrary, they are due to gain a good deal. Heretofore the State Medical Association has been contributing, from time to time, and as required, considerable sums of money to the State Board of Medical Examiners, to enable that body to administer and enforce the Medical Practice Act. The outsider, enjoying the same privileges and presumably burdened with the same responsibilities to insure to the public an adequate medical profession, has been paying nothing. These will now pay their share. In addition, and what is more to the point, it will now be possible, any day of the year, to determine just who is practicing medicine in this state, according to law, and where. That has never heretofore been the case. It will enable the law enforcement authorities to separate the sheep from the goats without any difficulty.

"There are many practitioners of medicine in this state who have never qualified for practice under the law. These will now be made to qualify or desist. That is to say, they are due to be made to do so. With the money accruing to the Board from the registration fee, the task should not be an impossible one. Indeed, it is believed by those who have studied the situation, that the task will be much easier than many of us think for."

Another editorial, a page or two further on, comments on the reduction of state dues as follows:

"It will be remembered that dues for 1932 are \$8.00 instead of \$10.00, plus, of course, the charge to cover county and district expenses. That represents a twenty

per cent reduction in the cost of membership for quite a large proportion of our members, and a twenty per cent reduction of income from that source for the Association. The trustees are finding it rather difficult to carry on the work of the Association without curtailment, on the reduced income, which is another good reason for asking early and prompt payment of Dues, Do It Now."

GRADUATE EDUCATION IN GEORGIA

Graduate education in Georgia is described editorially in the *Journal of the Medical Association of Georgia* as follows:

"The extension course for the physicians of Georgia, put on by the University of Georgia and Emory, was held in six sections of the State. The number of attendants at each course was as follows: Athens, 76; Waycross, 37; Swainsboro, 45; Albany, 60; Macon, 31, and Rome, 66, making a total of 315 physicians attending.

"The alumni and venereal disease clinic week was attended by 199 physicians. This gave us a total of 514.

"Through the cooperation of Emory University and the Julius Rosenwald Fund a five-day course of instruction was put on for the negro physicians. The enrollment was fifty-three, fifty being in attendance for each of the five days.

"This makes a grand total of 567 physicians who have attended classes by the professors of the University of Georgia and Emory.

"In all of these courses the State Board of Health had charge of the detail and publicity work.

"Prof. J. R. McCord, of Emory University, did a great deal to make the courses a success, giving much time to the details of the program. The same is true of the service rendered by J. C. Wardlaw, of the University of Georgia.

Doctor or Sanitarium UNUSUAL OPPORTUNITY

A distinguished granite facade 2-story brick building in the West Bronx is now fully completed, ready for inspection and immediate occupancy. Each story has 6 rooms, extra lavatory and basin, also open sun porch to the rear. Large foyers suitable for waiting rooms. Drop living rooms with indirect lighting. Walnut and maple floors, textured walls and beamed ceiling, lower floor and vaulted ceiling upper floor, ornamental wrought iron gates connecting with dining rooms, Spanish arched doorways, wainscoting effect in dining rooms; tiled kitchen and bathroom, colored fixtures in bathrooms; shower stalls with glass doors. Basement has finished reception room, laundry, and oil furnace for heating hot water and incineration. Builder will make alterations to suit buyer's requirements. Satisfactory terms may be arranged. Write Sabyrde, Realty, Inc., 2310 Third Ave., New York, or telephone HARlem 7-0102.

MEAD'S 10 D COD LIVER OIL IS MADE FROM NEWFOUND- LAND OIL

Professors Drummond and Hilditch have recently confirmed that for high vitamins A and D potency, Newfoundland cod liver oil is markedly superior to Norwegian, Scottish and Icelandic Oils.

They have also shown that vitamin A suffers considerable deterioration when stored in white glass bottles.

For years, Mead's Cod Liver Oil has been made from Newfoundland oil. For years, it has been stored in brown bottles and lightproof cartons.

Mead's 10 D Cod Liver Oil also enjoys these advantages, plus the additional value of fortification with Mead's Viosterol to a 10 D potency. This ideal agent gives your patients both vitamins A and D without dosage directions to interfere with your personal instructions. For samples write Mead Johnson & Company, Evansville, Ind., U. S. A. Pioneers in Vitamin Research. See page xvii.—*Adv.*

RESEARCHES IN CHEMISTRY

It can be said quite conservatively that chemistry affects every phase of our existence. Out of it have come wonders that stagger the imagination. The relationship between medicine and chemistry is a close one. The bacteriologist, the pharmacologist, the physician, and the pharmacist make daily use of their knowledge of chemistry. Without it, the work of Chen and Schmidt on the alkaloids of MaHuang could never have been accomplished.

For ages ephedrine-bearing ephedras have been native to China. The Pent-sao, or Chinese dispensatory, has long recognized the drug. It remained for Lilly modern research facilities to make available a line of ephedrine products, each item of which is suited to particular requirements. No one comparing the uncertain strength of a messy infusion of the ancient drug to the convenient forms in which Eli Lilly and Company make available the various ephedrine products—pure, potent, refined, and concentrated—would be inclined to doubt the progress that has been made in research organizations such as Eli Lilly and Company, or the part that chemistry has played in that forward movement. See page xvi.—*Adv.*

TRAUMATIC, INFLAMMATORY AND INFECTIOUS CONDITIONS

It would be difficult indeed to find a reputable work on medical treatment which does not contain favorable references to the application of moist heat in inflammatory and congestive conditions. Indeed, its use forms an important phase in the modern treatment of diseases and of injuries.

Exerting a powerful influence on the body in part and as a whole, the application of moist heat assists in repairing the tissues of the body, in relieving pain, increasing phagocytosis, diminishing congestion and in restoring function.

Wherever the application of moist heat is indicated, Antiphlogistine offers the physician a therapeutic agent capable of yielding optimum results. Due to the osmotic, hygroscopic and bacteriostatic action of its glycerine content, and to other ingredients entering into its composition, Antiphlogistine plays an important rôle in the modern treatment of a host of traumatic conditions such as sprains, contusions, fractures, traumatic arthritis, myositis; and in inflammatory and infectious conditions such as boils, sinusitis, bronchitis, tonsillitis, otitis media, various forms of arthritis, neuritis and local septic infections. Antiphlogistine is an essential remedy in the armamentarium of the physician and may be prescribed with confidence for all those conditions for which it is indicated.

Members of the medical profession are invited to write to The Denver Chemical Mfg. Co., 163 Varick Street, New York, for sample and literature. See page ii.—*Adv.*

ANNOUNCEMENT

The Department of Medicine of the New York Post-Graduate Medical School and Hospital of Columbia University announces the opening of a Clinic devoted to the study of the Capillaries in a variety of diseased conditions. Representatives of the following specialties will study the Capillary changes in the diseases in which they are interested:

Diseases of Metabolism.

Diseases of the Cardio-Respiratory system.

Diseases of the Endocrine Glands.

Migraine, Arthritis, Tuberculosis, and Allergic conditions.

Diseases of the Nervous System.

Surgical conditions of the extremities.

Cases or groups of cases of sufficient interest will be studied in greater detail in the Capillary Laboratory already established at this institution.—*Adv.*

Aurora Health Institute

Mendham Road, MORRISTOWN, NEW JERSEY

Beautiful country; elevation 700 feet; only one hour from New York. Open all year. Diet, electrotherapy and hydro-therapy. Personal medical supervision. Suitable for convalescence, compensated heart lesions, hypertension, rheumatism, diabetes, anemia, etc. Homelike atmosphere. No bed-ridden contagious or mental cases.

ROBERT SCHULMAN, M.D., Medical Director
Telephone—MORRISTOWN 3260

The Westport Sanitarium

WESTPORT, CONN.

An incorporated and licensed institution.
FOR NERVOUS and MENTAL DISEASES
ELBERT M. SOMERS, M.D., Physician in Charge. Located in an attractive private park on the Boston Post Road. Modern equipment. Adequate personnel and classification.

A BRIEF REVIEW OF THE PHYSIOLOGY OF THE GALL BLADDER*

By LESTER LEVYN, M.D., F.A.C.P., BUFFALO, N. Y.

THE functions of the gall bladder have been investigated from the seventeenth century to the present, but the very fact that there still remain so many puzzling uncertain factors is evidence of the complexity of that viscus.

Knowledge of the physiology of the gall bladder has made great strides during recent years, but even today there is much about this apparently simple organ that is baffling. It is known that the gall bladder stores and concentrates bile during the intervals of digestion and expels it into the intestines as required. Ordinarily, during fasting the gall bladder is distended with concentrated bile which tends to become inspissated if the vesicle fails to empty. During this process varying amounts of mucus are secreted. This mucus supposedly prevents excessive inspissation or acts as a lubricant to facilitate the expulsion of the concentrated bile during digestion.

In 1905 Hammarsten stated that the gall bladder concentrated the bile and he noted a marked difference between the weight of the dried residue of hepatic and gall bladder bile.

Rous and McMaster utilized an anatomical peculiarity of the hepatic ducts in the dog whereby a ligature placed at a certain point on the common bile duct allows bile secreted by one part of the liver to enter the gall bladder and from the remainder of the liver to be collected in a rubber bag. Using the concentration of pigment as an index they showed that bile which remains in the gall bladder for a number of hours is concentrated as much as ten times and that the mere passage of bile through the gall bladder may double or even quadruple the concentration.

Mann summarized the different views concerning other functions of the gall bladder as follows:

1. *The Reservoir Hypothesis*

It is evident that this view is tenable only in a restricted sense, but inasmuch as the great concentrating power of the organ is now generally known and accepted, it seems certain that the gall bladder does act in the role of a collector of bile.

2. *The Absorption Hypothesis*

There is definite proof of the absorption of water in concentrating the bile, but proof of absorption of cholesterol or other important biliary constituents is as yet inconclusive.

3. *The Secretory Hypothesis*

The epithelium of the gall bladder is not of the usual secretory type and, therefore, it is unreasonable to assume that the wall of the gall bladder secretes important substances into the bile, under normal conditions.

4. *The Bile-Flow Regulation Hypothesis*

This view by itself is inadequate except when included in that next to be described, viz:

5. *The Pressure Regulation Hypothesis*

This theory is reasonable to accept considering our knowledge of the concentrating power of the gall bladder and especially if we believe that the gall bladder acts as a reservoir to regulate the flow of a fluid constantly secreted by the liver, but only intermittently discharged into the duodenum. It is also reasonable to suppose that the gall bladder by slight contractions or relaxation may act as a buffer or pressure regulator of the biliary tract in respect of respiratory movements or changes in intra-abdominal pressure generally.

When the proper stimulus arises, usually as a result of the ingestion of food, the gall bladder contents are expelled in varying amounts over variable periods of time. Bile may be evacuated from the gall bladder almost as quickly as food begins to leave the stomach or it may be retarded for an hour or even longer after feeding.

Since it is known that emptying of the gall bladder is as a rule associated with feeding it is of interest to note which foods are most effective in stimulating evacuation of bile.

In 1923 Boyden in experimenting on cats discovered that feeding a mixture of egg-yolk and cream would induce the gall bladder to empty. This was verified by necropsy. Lean meat had less effect and rice scarcely any. In 1925 a group of men working in the surgical clinic of the Peter Bent Brigham Hospital discovered by means of the Graham-Cole method of cholecystography that

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 2, 1931.

a meal rich in fat would cause a marked reduction in size of the gall bladder shadow in man. Continuing their experiments they found that pure fat was most effective, protein considerably less so, and that carbohydrates were apparently ineffective to this end.

There has been much controversy over the question as to whether the passage of bile from the gall bladder is an active function of the musculature of the vesicle itself or whether it results from extrinsic factors. At present the weight of experimental evidence definitely indicates that the contents of the gall bladder are expelled mainly by the contraction of its own musculature. The wall of the gall bladder contains a large proportion of smooth muscle the function of which regardless of its distribution is contraction. Contraction in the gall bladder has been demonstrated frequently. That muscular contraction is capable of expelling the contents of the gall bladder has been demonstrated as follows:

A. The administration of smooth muscle stimulants such as barium chloride has produced expulsion of iodized oil.

B. Contraction rings in the vesicle have been demonstrated during evacuation of its contents.

C. Spasm has been noted during the process of emptying.

D. Elongation of the gall bladder occurs during emptying and relaxation during rest.

E. Actual measurements have shown a marked increase in pressure in the gall bladder after feeding.

F. Contraction after feeding with alteration in shape and reduction in size has been observed in the exposed viscus.

G. Peristalsis has been observed in the gall bladders of certain animals.

One good reason for doubting a passive mechanism for emptying the gall bladder is that an effective active mechanism has been demonstrated and another is that if the gall bladder emptied passively it would be the only hollow viscus in the body containing smooth muscle to function in this manner.

Extrinsic factors as effective expulsive agents can be ruled out for the following reasons:

a. Changes in intra-abdominal pressure such as might be due to respiration, have no effect.

b. Elimination of the sphincter of the common bile duct by cutting or an inlying tube or cannula produces no emptying of the gall bladder by elastic recoil or in any other manner.

c. Intestinal peristalsis has little effect because certain foods may pass through the alimentary tract without effect on the gall bladder. Drugs that stimulate peristalsis do not alter cholecystograms.

d. Administration of bile salts to induce increased flow of bile from the liver does not cause the cholecystogram to disappear.

e. The gall bladder shadow becomes denser as the vesicle becomes smaller in size after feeding.

f. The gall bladder empties normally after feeding fats even with the hepatic ducts tied off to prevent any washing-out effect of bile from the liver.

It has long been believed that the stimulus responsible for gall bladder evacuation is reflex, due to the presence of food or acid chyme in the duodenum and traveling over nerves to the gall bladder. While this theory has not been disproved the evidence available is largely against it. Denervation of the gall bladder does not inhibit normal emptying after feeding.

It has also been thought that there exists a reciprocal nervous mechanism whereby the gall bladder is made to contract when the sphincter of the common bile duct is opened.

This is contradicted because:

1. Duodenal peristalsis in itself which supposedly opens the sphincter does not induce the gall bladder to contract.

2. Opening of the sphincter by the administration of bile salts does not cause the gall bladder to contract.

3. The sphincter may be destroyed and yet the gall bladder contracts normally during digestion.

Is the motor stimulus to the gall bladder furnished by a hormone? It is difficult to conceive how it could be stimulated in any other manner, with the gall bladder denervated. Fats empty the gall bladder readily whereas proteins have but slight action and carbohydrates practically none. It has been shown experimentally in animals that one intravenous injection of only a few c.c. of highly emulsified olive oil or of egg-yolk induces as marked a response as the ingestion of a much larger amount of the same substance. In spite of this it does not appear that fat in the circulation is the real gall bladder stimulus as the gall bladder may empty without any increase of fat in the blood.

The presence in the circulation of a secretion like product developed by food or hydrochloric acid in the duodenum has been thought of as stimulating the musculature of the gall bladder. Emptying of the gall bladder has been induced by the intravenous injection of a purified fat-free extract of duodenal mucosa and by applying hydrochloric acid to the duodenal mucosa.

It has been shown that crossing the circulation in dogs by allowing the blood of one dog to flow into the vessels of another and applying decinormal hydrochloric acid to the duodenal mucosa of the one dog that the gall bladder of the other was found to contract. It would therefore seem that gall bladder contraction is brought about by the presence of some substance in the circulation, which theory is fortified by the knowledge that

the gall bladder will empty after feeding though denervated

However, the question still remains as to whether a specific hormone is produced by the action of hydrochloric acid in the duodenum or in some other manner

The intravenous injection of highly emulsified fat and extract of duodenal mucosa are equally efficient in emptying the gall bladder

Spontaneous emptying of the gall bladder has occurred even after days or weeks of fasting. The gall bladder has emptied even when the gastric contents have been strongly alkalinized

It seems reasonable to theorize that if gall bladder contraction is stimulated by a hormone developed by hydrochloric acid in the duodenum the stomach would play an important role, but certain workers have demonstrated that removing the stomach and anastomosing the esophagus and duodenum have not prevented gall bladder contraction after fats have been fed the animals

From the above it is apparent that the normal stimulus responsible for gall bladder contraction has not as yet been conclusively demonstrated

One of the most important functions of the gall bladder is that of concentration. Water is readily absorbed. The concentrating function enhances the function of the viscus as a storage reservoir but if normal emptying does not occur over concentration and precipitation may result

Another important function is that of the secretion of mucus. The gall bladders of normal experimental animals are found to contain mucus in large or small amounts. In some instances the vesicle has been filled with almost pure mucus containing only a small quantity of bile

The three significant functions of the gall bladder therefore are

1 The evacuation of its contents brought about by contraction of its musculature

2 Concentration of its contents through the absorption of water

3 The secretion of mucus

Some workers have shown that dyes placed in the lumen of the gall bladder find their way into the lymphatics and that there is a probability that cholesterol is also absorbed from the bile. It is

uncertain, however, if this is a normal function or if this phenomenon indicates very early gall bladder disease

The earliest pathologic changes in the gall bladder undoubtedly are directly related to disturbance of function and cholecystography is of inestimable value as a functional test

Boyd advanced the theory that cholesterol is absorbed from bile by the mucosa until pedunculated masses are developed in the rugae which eventually break off and form the nucleus of cholesterol gallstones. He also contends that the formation of stones is due to the deposit of cholesterol in the mucosa from an overloaded bile, the function of the mucosa being altered by inflammatory changes

If stasis of the bile occurs with no undue increase of cholesterol active concentration may induce precipitation of other constituents of the bile with the formation of other types of stones

ACUTE POLIOMYELITIS NAMES AND SYNONYMS—INFANTILE PARALYSIS: HEINE-MEDIN DISEASE

By IRVING PARDEE, M D, NEW YORK, N Y

ACUTE poliomyelitis is an acute generalized infectious disease which occurs both sporadically and in epidemics affecting largely children and adolescents. A characteristic paralysis ensues in the majority of instances, due to the selective pathological localization in the cells of the anterior grey column

The first accurate description of this disease

was made by Von Heine¹ in 1840, though paralyzes, indefinite in type, were described in the 17th and 18th centuries. The focal lesions in the anterior horn were noted by Prevost and Vulpian and later Strumpell² in 1884 described the infectious nature of the disease. The name poliomyelitis (polios grey) was suggested by Kussmaul who was impressed by the lesions in the grey

matter. Very little further progress in the understanding of the disease was made until Medin³ in 1890 studied current epidemics and gave the first good clinical description of its course. Because of the undoubted contributions of these writers the disease has become known as Heine-Medin disease, especially in Europe, although the designation of Acute Poliomyelitis is urged by the United States Census Bureau. Large epidemics occurred in Norway and Sweden and we are indebted to Wickman⁴ for so complete a report of the disease after these epidemics that little advance has been made since.

In this country there were sporadic small groups of cases occurring for twenty years before the larger epidemic of 1907. Since that time the disease has been endemic so that every year or so there occur outbreaks in different states, the largest occurring in the summer of 1916. There was a total of 27,000 cases reported with 6,000 deaths,—half of these were in New York City alone.

ETIOLOGY

Susceptibility to the disease is noteworthy between the ages of one to five years, during which period 75 per cent of the cases occur, while 95 per cent have occurred under sixteen years of age in certain epidemics. Contact infection is considered to be very rare, though the report of the New York Committee⁵ which studied the large 1916 epidemic extensively, is of interest in this regard. Children's institutions and separate communities such as the military post on Governor's Island were isolated during the epidemic with the result that no cases occurred. However, there are numerous reports of two, three, and even five cases in one family. The seasonal occurrence of poliomyelitis is of note, July, August, September and October being the months when the disease is at its height.

An extensive literature has developed on the subject of the mode of transmission of the disease, but we are yet far from a final conclusion. Milk-borne epidemics are reported here and in England. The common fly is also accused of being the carrier of this disease, but only further studies will serve to elucidate this important factor.

The virus of the disease is present in the nasopharynx of humans, and remains so for months or years following the infection. The upper respiratory tract is considered the site of entrance of the virus and the infundibulum is the pathway for cerebral involvement, according to Marinесco⁶.

Experimental transmission of the virus of the disease was first successfully performed intraperitoneally by Landsteiner and Popper⁷, while Flexner and Lewis⁸ injected suspension of central nervous tissue into the brain of monkeys. Thus it was found possible to establish a strain of the

virus which was passed through several hundred animals who presented a picture of the disease. By means of this it seems conclusively proven that it was a living virus and not a toxin of the disease. No stainable organism has been found, but it has been proven by experiments that it is filter-passing and ultra-microscopic. Flexner, Noguchi and Amoss⁹ found uniformly what they termed globoid bodies which produced experimental poliomyelitis in monkeys. However, it has been impossible to establish their relationship to the virus, or as the causative agent in human poliomyelitis.

A polymorphic streptococcus-like organism has been isolated and described by Rosenow, Nuzum and Mathers¹⁰, but other research studies have failed to confirm their work, so doubt may be cast upon the specificity of this organism in poliomyelitis.

Until further research reveals the real facts as to the organism and its mode of transmission, we remain still pathetically in the dark as regards a solution of the problem of this disease.

PATHOLOGY

The gross appearance of the brain and spinal cord at autopsy is notable only for edema, congestion of the capillaries, and scattered petechial hemorrhages. The meninges may likewise show congestion. On cross-section of the spinal cord the greatest involvement is seen in the lumbar and cervical grey enlargements, no doubt due to their greater blood supply. Here an occasional capillary hemorrhage is seen with all degrees of destruction up to a hemorrhagic myelitis.

Microscopically, the outstanding lesion is a round cell infiltration, especially around the pial vessels. In the posterior root ganglia there is nerve cell destruction and lymphocytic infiltration. Of note is the interesting observation by Amoss¹¹ that this is the first nervous tissue attacked and also the first to recover, which allows one readily to understand the distressing hyperesthesia present early in this disease.

The white matter in the cord shows perivascular infiltration, while the grey matter is most strikingly involved in both posterior and anterior horns. There are observed focalized and diffuse infiltrations of round cells, while the nerve cells first show edema, granulation of the cell protoplasm, neuronophagia, with final scar tissue replacement of the neurone. The early edema of the cell is considered to be the cause of the initial paralysis while the rapid recovery of the muscle is explained on the subsidence of its swelling.

The distribution of the lesion especially in the lumbar and cervical cord enlargements has already been noted, but also there are frequent changes in the medulla in fatal cases. Likewise lesions are seen in the subcortical region in certain cases.

In recent years considerable interest has been aroused over the visceral lesions observed in this disease. A hyperplasia of all the lymphatic structures of the body is generally noted, the histological picture resembling typhoid fever. Occasional necroses are found in the liver and lymphatic nodules. Observations on the total pathology of poliomyelitis would indicate that there is a generalized disease affecting the parenchymatous organs and lymphatic tissues with a special preference for the central nervous system.

SYMPTOMATOLOGY

The incubation period of poliomyelitis is short, averaging about two weeks, but three to ten days is more usual. Rare cases have developed within twenty-four hours after exposure.

The onset is usually sudden with symptoms of a generalized infection. The child feels out of sorts, has no appetite, and wants to do nothing. Fever develops almost immediately, though it is 101 to 103 degrees, it may be very transitory over night, or it may last until the fourth or fifth day with return to normal temperature. The pulse is rapid, more so than the fever would warrant. With the onset and in the first few days, there may be a convulsion, though it is rare, but nausea, vomiting, constipation or diarrhoea are commonly observed symptoms. This initial period may pass rapidly and should no paralysis occur it might have been unrecognized.

Meningeal irritative signs are frequently seen at an early stage with the occurrence of stiffness of the neck.—Kernig and Brudzinski's sign. Headache is often very troublesome, and of note is the distressing pain at the back of the neck and between the shoulders. This often gives the impression of rigidity, but is really not a true sign, only another evidence of the pain and hyperesthesia. Pain is a troublesome symptom for it not only occurs spontaneously and on movement, but deep pressure reveals an acute sensitiveness. Sedatives frequently must be given for this. Hyperesthesia of the skin is exceedingly uncomfortable and may last five to ten days. Profuse sweating or flushing of the skin may occur. Paralysis of the bladder is rare. The tendon reflexes are often exaggerated early but later on as the paralyses occur, inequality or a complete loss may be present in the paralyzed group of muscles.

Paralysis, the outstanding symptom of the disease, has its onset in seventy per cent of the cases before the fourth day. It is not essential for the diagnosis of the disease, as it is only a symptom in the course of an infectious process and many abortive forms will be recognized by early spinal fluid studies. The paralyses are often preceded by twitching of the muscle groups which later show paralysis. The most frequently involved groups of muscles are in order,—those about the hips, the legs (both about equally), and the arms, (more often one). Often it is difficult

to determine which muscles are paralyzed because portions of several muscle groups are involved rather than any single muscle. An anatomical explanation for this clinical finding is the knowledge that the cells in the cord are arranged vertically through several segments while the vessels around which the infection centers are arranged horizontally. It is frequently necessary to stimulate the limbs of young children with a pin to make them move, in order to determine the amount of paralysis. The back muscles are very often paralyzed and when recovery takes place, it may do so unilaterally, resulting in a scoliosis.

Cranial nerve paralyses are not infrequent. Radovici¹² having reported fifteen cases of isolated facial nerve paralysis.

We have seen in the foregoing description that the disease may be differentiated into three stages, one of general infection, one of invasion of the subarachnoid space, and lastly invasion of the neuraxis itself. Its progress may become arrested at any stage and only in the latter will paralysis occur.

There is much discussion in the literature on the subject of separating poliomyelitis into several types, but it seems quite futile, for it only confuses the clinical approach. If we consider that the picture presented by the patient depends upon the location of the involvement of the nervous system, it brings to the mind a clearer concept of its anatomical pathology. Those cases in which meningeal signs predominate have been noted, while the bulbar type is one of extreme gravity. In this the medulla is chiefly involved, with rapid heart, difficulty in swallowing and respiratory paralysis often resulting in fatality. A so called encephalitic form is seen in which there is a clouded sensorium, delirium, or stupor, and often a paralysis of a spastic type (upper motor neurone pyramidal lesion). This form usually has a favorable outcome.

The well known syndrome of Landry's ascending paralysis has become of late more and more referred to as a form of poliomyelitis. In this condition there is a successive involvement of the legs, trunk, arms and lastly the bulb with fatal termination. More rarely a descending type is seen, which bears a good prognosis. A careful differentiation must be made from similar clinical types of epidemic encephalitis, toxic myelitis, or polyneuritis.

Abortive forms of this disease are seen in large numbers in epidemics, more probably because they are better recognized than these may or may not show meningeal signs and do not develop paralysis. Potts described a peculiar form of intrauterine poliomyelitis.

Diagnosis. Examination of the patient is of great value in coming to a diagnostic conclusion. Close observation must be made for respiratory

paralysis, e.g., of diaphragm and intercostals, and for abdominal wall weakness, etc. The back, as before noted, is very painful, and being supported stiffly on movement gives the impression of cervical rigidity, which is not a true sign. Careful neurological examination is essential to determine the quantity and location of parenchymatous involvement of the spinal cord and brain. Thus only can the progress of the disease be determined.

Spinal puncture is one of the most important diagnostic aids in poliomyelitis and should be performed early and repeated frequently. The pressure is uniformly increased. The color of the fluid is clear, opalescent, or rarely yellow and a fibrin web may form on standing. Albumin and globulin are increased and Fehling's is reduced well. The number of cells is apt to be high in the early stages, from 100 to 1000, and there is a preponderance of lymphocytes, 75 to 90 per cent, according to various estimations. Menninger¹² says that within the first twelve to twenty-four hours the polymorphonuclear leucocytes predominate. Large mononuclear and endothelial cells are frequently found. After the first week the cell count returns to normal. The colloidal gold curve is usually of the luetic type, and the blood picture of this disease is one upon which observers are evenly divided, e.g., as to whether there is a leucocytosis or a leukeopenia. A relative lymphocytosis is also noted. The urine shows no variation.

Differential Diagnosis

(A). Epidemic meningitis. True rigidity of the neck combined with marked Kernig's sign in a patient usually very much more acutely ill is found. The spinal fluid shows a higher cell count with considerable polynuclear increase and a marked decrease in globulin.

(B). Tuberculous Meningitis. A history of a slow onset with headache, continuing fever and obvious meningeal signs. The early spinal fluid examinations are the same, but later the globulin is much increased, and sugar reduction is diminished.

(C). Epidemic encephalitis is characterized by a diffuse lesion with an associated stupor and lethargy; the encephalitic form of poliomyelitis is only seen in the presence of an epidemic. The cell count in the spinal fluid is low, 0 to 150, and is normal in 50 per cent of the cases.

TREATMENT

The treatment of poliomyelitis falls naturally into three stages: (a) acute stage; (b) convalescent stage; (c) chronic stage.

In the acute stage the therapy is general and specific. The former is directed to a symptomatic approach, the most important factors being absolute rest and quiet. Hyperesthesia, which is so distressing a symptom, must be re-

lieved by protecting the sensitive skin with cotton, while the pain is best combated by codeine or morphine. When the respirations are embarrassed morphine will often give much needed rest. Muscular rest for the weak or paralyzed muscle so as to relieve strain is essential, while support for the back and neck, which are exceedingly sensitive, is productive of much comfort.

Warm salt baths should be given as soon as the pain and tenderness have disappeared, combined with slight under-water movement. Medical therapy has proven of no avail, though hexamethylamine has been tried internally and adrenalin hypodermically and intraspinaly.

Spinal puncture as a diagnostic procedure is of great value, but the author, Menninger¹⁴, Dively¹⁵ and Crothers¹⁶ strongly believe also in its efficiency as a therapeutic agent, combined with spinal drainage.

The paralyzes must be treated with rest. Support of the tension on the muscles and the limbs is of great importance and no massage should be given until after three or four weeks. Lovett¹⁷, whose wide experience in these cases has resulted in making many advances, has noted "muscles are more often weakened than totally paralyzed." Therefore the muscle must not be fatigued or strained.

Serum Therapy. (a) Prophylactic. Convalescent serum has been largely used in animal experimentation where it has proved somewhat effective. In human poliomyelitis, however, it has proved impracticable. The most effective method of prevention is to avoid contact with body secretions, especially nasal secretions. Good respiratory manners must be cultivated, especially around children, who should be avoided. Nasal douches have been recommended. Isolation in the presence of epidemics is the most effective method to avoid infection. Three to six weeks' quarantine for recovering cases, while contacts should be quarantined for two weeks.

(b). Serum treatment of acute cases. In animal research it was found that monkeys who had recovered from the disease could not be reinfected. Netter¹⁸ was the first to supply serum therapy to human cases. Convalescent blood serum has been quite largely employed and it should preferably be obtained from recently recovered cases. If possible, several sources may be successively used in one case with advantage. Flexner and Amoss¹⁹ showed that poliomyelitis antibodies in the blood would pass into the spinal fluid if the meninges were inflamed, and it is generally recommended that both intraspinal and intravenous injection be made. If necessary, the injections may be made every twelve hours—the intraspinal injection to be 15 to 30 c.c., and the intravenous 50 to 100 c.c. in order to obtain the maximum benefit. Much emphasis is made upon the early administration of the serum, as cases

treated within forty-eight hours of the onset would seem to have the best chance of improvement.

The horse serum prepared from Rosenow's streptococcus has been extensively used, but there is still a strong skepticism concerning it.

The entire question of serum therapy will be subject to further review at a far later date as it is still in the experimental stage, and whether it has a specific effect or is due to a non-specific protein influence is yet to be proven. However, in so serious a disease, where at best the approach is inadequate, anything which holds out hope is worth a thorough trial.

A recent suggestion in treatment by Bordier²⁰ is radiotherapy applied according to his special technique to the spinal cord level involved. Diathermy to the affected muscles combined with low voltage current of desired frequency and wave form continued over a long period has been suggested. Numerous other contributors have reported success with radiotherapy given early.

Treatment during the convalescent stage is carried out as follows: Rest must be continued until tenderness is gone. Muscles weak or paralyzed must not be allowed to be stretched nor must fatigue occur. Walking must be encouraged as soon as possible, and no deformity must be allowed in any position, either lying in bed, sitting, or walking. Lovett¹⁷ and Wright²¹ have stressed in their writings that muscle training is the most important factor in recovery and deformities must be prevented. Massage is of inestimable value after the first month, and should be regularly employed to improve the circulation and support the muscle tone. Heat locally applied is also of benefit and faradism to cause complete muscle contraction may be helpful, but must not be given too strong.

Spontaneous improvement will continue for several years and operations should be put off till the maximum recovery has taken place and the condition is permanent. Treatment in the chronic stages is a problem of correction of deformities by operation and the proper application of braces. Only a well trained orthopedic surgeon with a thorough knowledge of the mechanics is capable of properly carrying this out.

PROGNOSIS

The mortality in this disease varies greatly, depending upon whether or not an epidemic is in progress. In the New York epidemic of 1916⁶ the rate was as high as seventy-seven per cent, while the average could not be more than ten to twelve per cent. It is highest in adults and in the bulbar forms of the disease.

The expectancy of paralysis is a much mooted question, the statistics varying from sixteen per cent to forty-four per cent which will recover completely without residual paralysis. Again the

figures of the New York epidemic show that in 1223 reported cases, sixty-seven per cent had residual paralysis. Recovery from the paralysis depends largely upon the type of care which the patient receives. The chances of functional recovery are six to one in cases with proper muscle training, under guidance of an expert; otherwise it is three to one. These figures of Lovett and Martin are very important and striking.

In conclusion, the best prognosis is obtained by proper treatment, and avoidance of infection, during an epidemic, by isolation.

PROVISION FOR THE TREATMENT OF THE SYPHILITIC AND GONORRHEIC

By ALBERT PFEIFFER, M.D., DIRECTOR, DIVISION OF SOCIAL HYGIENE, NEW YORK
STATE DEPARTMENT OF HEALTH, ALBANY, N. Y.

PHYSICIANS frequently write the Division of Social Hygiene asking how they are to receive payment for the treatment of the indigent syphilitic and gonorrheic. Section 343-p of the Public Health Law as amended April 13, 1931, is as follows:

"Any person who is suffering from a venereal disease who is unable to pay for treatment may make application for care and treatment to the board of health or health officer of the health district in which such person resides, and such board or health officer shall promptly institute treatment. It shall be the duty of each county and city board of health to provide facilities adequate for the diagnosis, care and treatment of persons suffering from venereal disease, who are unable to pay for treatment by a private physician, which facilities shall meet such standards as may be prescribed by the state commissioner of health."

This section places the responsibility upon local health departments of providing treatment for any case of gonorrhea or syphilis unable to pay irrespective of whether the case is infectious or otherwise. Provision in the law has therefore been made to take care of the paretics, tabetics, the congenital and cardiovascular cases.

It will be noted that the word "indigent" has been changed in the amended law to "who is unable to pay" and this term is interpreted as applying to patients who cannot pay customary fees for the continued treatment which is usually necessary. The Department is much concerned with the inadequate treatment of not only the indigent but of patients able to pay but a dollar or two for their treatments which for the best interests of themselves and the community should extend for a year or more.

Our studies show that the vast majority of patients with syphilis are not diagnosed until comparatively late in the disease. In the interest of the patient, the objective is mainly to prevent degenerative changes and possible premature cardiac death, but from the point of view of the tax payer, whom the state represents, the objective is the prevention of tabes, paresis and blindness requiring institutional care, a big factor in our cost of government.

Many health officers have arranged with their boards of health to pay practicing physicians a nominal sum ranging from \$1.50 to \$5.00 per treatment. Physicians having patients unable to pay regular fees for extended treatment must receive authorization from their local health officer and have a fee arranged before a claim can be made. Having all of these patients come at a definite time every week is usually most convenient and effective, and when the number of cases warrant it, the establishment of a treatment center or clinic is indicated as an economical measure. It is often noted in places where the health officer selects a practicing physician to see indigent cases and a treatment center is established, that a physician will raise objections to so-called clinics, but nothing is said regarding the previous neglect in diagnosing and adequately treating these cases, the result often being that they become derelicts and charges on the community.

The State Health Department supplies to up-State physicians for the treatment of these cases, bismuth in both the soluble potassium sodium tartrate form and the insoluble salicylate, arsphenamine, sulpharsphenamine and to a limited degree tryparsamide.

LEPROSY IN A CHILD

By I. NEWTON KUGELMASS, M.D., NEW YORK, N. Y.

(From the Department of Pediatrics, The Fifth Avenue Hospital, New York.)

TROPICAL diseases should always be considered in the analysis of atypical manifestations in recent arrivals from foreign lands. Since the influx of children from southern countries there has been a great stimulus in the study of diseases occurring amongst them in their native habitat because of the problems their clinical conditions have presented on admission to the hospital. Our eyes have thus been opened to striking deficiency diseases, strange infectious diseases and severe alimentary disturbances. The present case is illustrative of what might have been considered luetic in the light of the clinical

manifestations only to be confirmed by a positive Wassermann which not infrequently occurs in leprosy.

Edith S., a ten-year-old girl, was admitted to the hospital August 6th, two weeks after her arrival from Porto Rico. She had been ill for three months with a patchy, erythematous rash over the trunk, buttocks and extremities and a thickening of the fingers which interfered with their usefulness. As far as it was possible to ascertain from her parents she had had no fever, alimentary upsets, pains, respiratory or infectious disturbances. The parents were more concerned about the unaesthetic

appearance of the child's body rather than about any severity of the child's illness. There was no history of contact with anyone of equivalent symptomatology.

The girl was fairly nourished, alert, responsive. The reflexes were normal. The pharynx

were yellowish in the center and bright red at the border, distinctly dry, smooth and shiny. Some of the macules appeared pale in the center tending to clear up but most of them were distinctly anesthetic to the prick of a pin.

FIGURE 1
Patchy Pigmented Erythema

was ingested and there was some cervical lymphadenitis. The heart was normal; the lungs were clear; the abdomen was soft; the spleen was palpable and the liver was not enlarged. She showed a generalized maculopapular eruption especially profuse over the buttocks and lower extremities. The macules

FIGURE 3
Contractures and Thickening of Fingers

Over the lower extremities were several round nodules varying in size from a small shot to a filbert. They were raised above the level of the skin, elastic to the touch but anesthetic to the prick of a pin. The face was free from lesions and the eyelashes, eyebrows, conjunctiva and mucous membranes were unaffected.

Roentgenograms of both hands showed no bone or periosteal changes. There was a swelling of the soft parts particularly over the middle portion of both little fingers, more marked on the right than on the left side. The film of the chest showed a marked thickening about both roots; the peribronchial markings were accentuated particularly on the left side. The appearance was that of an acute infectious process. The Wassermann and Kahn reactions were negative. The blood showed a hemoglobin of 86 per cent; red cells 4,400,000; white cells 8,000; polys 37 per cent; lymphocytes 51 per cent and eosinophiles 12 per cent. The urine was normal in every respect. Biopsy of one of the nodules failed to show the acid-fast lepra bacilli, but the inflammatory process was characteristic. Attempts at isolating the organism from the nasal discharge were also without avail.

We are indebted to Dr. W. E. Woodbury and to Dr. F. E. Bartlett for their clinical contributions; to Dr. Howard Fox for the dermatologic consultation and to Dr. D. J. D. Jessup for the pathological examination.

FIGURE 2
Tubercular Nodules of Leprosy

RESULTS OF A RECENT HYGIENE EXAMINATION

By PAUL B. BROOKS, M.D., ALBANY, N. Y.

Member of the State Board of Medical Examiners.

A STUDY of papers in hygiene submitted by 155 candidates in the last State medical licensing examination raises some interesting questions as to what recent medical graduates do, and should, know about hygiene and public health. The public is accustomed to look to practicing physicians for advice and guidance in this field, and practically all medical schools in the State have undergraduate courses covering it.

The examination questions, summarized, were as follows:

- (1) Difference between active and passive immunity, with examples.
- (2) Four physical defects commonly found among children entering school and likely to impede progress.
- (3) Which one of the several vitamins present in milk is destroyed by pasteurization and how may it be replaced in the diet of the infant?
- (4) Three diseases in which sore throat is an early and prominent symptom.
- (5) What is meant by "Preventive medicine"?
- (6) What is the state sanitary code? By what official body is it enacted?
- (7) Purpose of Schick, Dick and tuberculin tests.
- (8) Two important features in construction of a sanitary privy.
- (9) Would you advise an apparently healthy adult to have periodic physical examinations? Explain answer.
- (10) Ages of greatest susceptibility to diphtheria and means of providing protection.
- (11) Mention two possible explanations of a failure to secure a "take" in vaccinating a person who has never had smallpox.
- (12) Three diseases apparently incited by the hemolytic streptococcus.

The candidates had a choice of ten questions.

That the examination was relatively easy was indicated by the fact that only 15 out of 155 failed to attain a pass-mark of 75. Two rated 100%, a mark attained by none of the more than 400 candidates in the June examination; 38 received marks of 90% or over; 24 received marks of 75%.

The most striking observation was that 132 of the 155 candidates "passed up" question number 6. Of the 23 who attempted to answer it, not one answered it correctly and only one or two approximately correctly. Yet the sanitary code im-

poses important duties on physicians practicing everywhere in New York State, excepting in New York City. Inability to answer this simple question might be explained on the assumption that most of the candidates lived in New York City, where the State code is not effective; still, if they had had any knowledge of the nature and origin of the New York City sanitary code they could have made a better guess as to the answer than most of them did.

Fifty passed over question number 12,—three diseases apparently incited by the hemolytic streptococcus; and 31 answered it incorrectly. Even without courses in public health it would seem that the average medical student, somewhere in his course, would have stumbled upon the relationship between the hemolytic streptococcus and scarlet fever, septic sore throat, and erysipelas.

The question avoided by the next largest number, 37, was number 3: the one vitamin in milk destroyed by pasteurization. It was answered correctly by 42 and fifty percent correctly by 18 others. The answers of 37 were wholly wrong. This result is interesting because physicians are frequently called upon for advice as to the relative virtues of raw and pasteurized milk and it is not unusual to find one advocating raw milk because "all the vitamins are intact."

Perhaps of greater practical significance was the fact that 33 passed over the question on vaccination, and only 86 answered it either correctly or approximately correctly. This certainly is a matter upon which every physician hoping to practice medicine should be thoroughly informed.

Fortunately there is "another side to the picture." Nearly all candidates selected question number 1 and answered it correctly. I question whether, five years ago, many would have been able to give a clear explanation of the difference between active and passive immunity. A large majority selected and answered approximately correctly the questions on physical defects in school children, preventive medicine, diphtheria in children and purposes of Schick, Dick and tuberculin tests.

Another interesting point was that nearly all answered the question regarding periodic physical examinations and without exception stated that they would advise such examinations, giving valid reasons for this position. I feel certain that if this question had been presented a few years ago many would have answered in the negative.

THE MICROSCOPIC SLIDE PRECIPITATION TEST FOR SYPHILIS WITH SPINAL FLUID

A Comparative Study with 500 Spinal Fluids

By JOSEPH JORDAN ELLER, M.D., AND CHARLES ROBERT REIN, M.D., NEW YORK, N. Y.

From the Department of Dermatology and Syphilology, New York Post-Graduate Medical School of Columbia University. Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 2nd, 1931.

THE microscopic slide precipitation test for syphilis with spinal fluids has been found by us to be more sensitive than the Wassermann reaction, Kahn test, albumin-globulin ratio and colloidal gold reaction. The purpose of this paper is to present a comparative study of this test with the accepted complement fixation and precipitation tests with special emphasis on the agreement of the tests with clinical findings.

This precipitation test recently described by one of us¹ is simple in detail, requiring no titrated hemolytic system of cells, amboceptor or complement. Furthermore, it requires no concentration of the globulins of the spinal fluids, it is performed with antigen emulsions that are satisfactory for use for twenty-four hours, and the results of the reaction magnified about 120 times by the microscope are read accurately with ease."

The spinal fluids were obtained from hospital and private practice and also from Dr. Leo Spiegel. The majority of the fluids were derived from cistern punctures which yielded sufficient material for the various tests employed in this series.

The patients were divided into a neurosyphilitic and non-neurosyphilitic group. The latter was comprised of patients with systemic syphilis but no evidence of central nervous system involvement and patients who presented themselves for syphilitic investigation who proved to be negative both clinically and serologically.

The microscopic slide precipitation test for syphilis with spinal fluids was performed according to the technic described¹ with the Kline antigen,² as follows:

"PRELIMINARY PROCEDURES WITH SPINAL FLUIDS

"Spinal fluids turbid with blood, exudate or bacteria, or containing injected substances including horse serum are unsatisfactory for testing. Spinal fluids with slight turbidity of few particles are centrifuged at high speed for ten minutes and the clear fluid withdrawn or decanted. All clear and cleared spinal fluids are tested as follows:

"Place the required number of test tubes 6 x 5/8 inch each containing 5 c.c. of Benedict's solution (1926) in a beaker (Pyrex). Add water halfway to the top. Heat. Keep the tubes in vigorously boiling water five minutes.

"Place the tubes in a rack. After making certain no copper reduction has occurred in any of

the tubes, add to each tube properly numbered 0.5 c.c. of spinal fluid. Shake the tubes individually vigorously for ten seconds.

"Replace the tubes in the beaker. Add water halfway to the top. Heat. Keep the tubes in vigorously boiling water five minutes.

"Replace the tubes in the rack, inspecting each immediately upon removal from the beaker for precipitate indicating presence of sugar.

"Spinal fluids giving a negative reaction for sugar in the above test are unsatisfactory for testing for syphilis. These are fluids that have been acted upon by bacteria either inside or outside of the body. In the former case of the various bacterial meningitides in which organisms and ferments of the exudate have acted upon the sugar, the fluids may contain substances giving positive or unsatisfactory reactions in various tests for syphilis. In the latter case of bacterial contamination subsequent to withdrawal, spinal fluids from cases of syphilis show a steady loss both of sugar and of the specific reacting substance if the fluids are kept at room temperature.

"On the other hand spinal fluids containing sugar when withdrawn from the body kept at low temperature (8 degrees to 12 degrees C.) continue to give a positive reaction for sugar with the test described above for several weeks, and syphilitic spinal fluids under these conditions show no appreciable loss of specific reacting substance for at least a week.

"The clear and cleared spinal fluids which give a positive reaction in the sugar test described above are then tested as follows:

"MICROSCOPIC SLIDE PRECIPITATION TEST FOR SYPHILIS WITH SPINAL FLUID

"Into each of twelve chambers on six glass slides, deliver 0.05 c.c. of 1 per cent glacial acetic acid solution from a 0.2 c.c. pipette graduated in thousandths.

"Into each of the twelve chambers allow 0.25 c.c. of the spinal fluid to be tested to fall from a 1 c.c. pipette graduated in hundredths (six fluids in duplicate). Hold the pipette directly above the acid and lastly touch the tip of the pipette at some dry portion of the chamber.

"Rotate the slides in a holder on a flat surface with moderate vigor for one minute.

"One drop of the diagnostic test antigen emulsion (about 0.0075 c.c.) is allowed to fall from a Wright pipette into one half of the fluids. Into each of the other six duplicate fluids a similar

drop of the exclusion test antigen emulsion is allowed to fall.

"Rotate the slides in the holder on a flat surface with moderate vigor for one minute to distribute the antigen and then for four minutes move the holder gently, but rapidly (about three complex movements a second), back and forth a distance of one-fourth to one-half inch.

"The results are examined at once through the microscope at a magnification of about 120 times (eyepiece 12X, objective 16 mm.) with the light cut down as for the study of urinary sediments and recorded in terms of pluses according to the degree of clumping and the size of the clumps. For ease in reading the results, the slide is tilted on a piece of metal one-eighth inch thick, one inch wide and four inches long, placed on the stage."

The Wassermann tests were performed by Drs. Osamu Ishii and Eugenia Trouveller at the New York Post-Graduate Hospital Laboratories. Two antigens were used, one an alcoholic extract of beef heart and the other a similar antigen reinforced with 0.2 per cent cholesterol. The tests with both antigens were kept in the ice-box overnight for the period of fixation.

The Kahn tests were performed by Dr. Osamu Ishii³ according to the modified technic described by him.

The albumin-globulin ratios were performed by Dr. Leo Spiegel according to the technic described by Exton and Rose.⁴

The colloidal gold reactions were done according to the standard technic, with colloidal gold solution prepared by the method of Wuth and Faupel.⁵

RESULTS

Table I shows the very close agreement (94.80%) of the diagnostic microscopic slide precipitation test with the clinical findings of the patients. The one false positive (a two plus reaction) occurred in a case of tuberculosis meningitis.

One doubtful reaction (one plus) occurred in a patient with epileptiform attacks but with no evidence of syphilis. There were twenty-four negative reactions in cases which had been diagnosed as some type of neurosyphilis. Sixteen of these cases had received considerable treatment and were not only negative in the diagnostic slide precipitation test but were also negative in all the other spinal fluid procedures including the non-cholesterinized and cholesterolized Wassermann, colloidal gold reaction and total protein-globulin ratio.

Table II correlates the results of the exclusion microscopic slide precipitation test with clinical findings. In this series the total agreement (95.6) is slightly higher than with the diagnostic antigen. There were 16 fluids with negative reactions from patients who had been diagnosed as neurosyphilitics and were under treatment. Fourteen of these cases were negative by other spinal fluid findings including the cholesterolized and non-cholesterinized Wassermann reactions, colloidal gold reaction, albumin-globulin ratio, and cell count. The other two gave positive Wassermann reactions but were negative with the colloidal gold reaction. There were three false positives, one occurring in a case of tuberculosis meningitis and two in patients with epilepsy.

Table III summarizes the increase in sensitivity of the exclusion slide test over the diagnostic slide test. There was an increase of 6.4% in the strongly positive cases while there were ten more negatives with the diagnostic procedure than with the exclusion test.

Table IV shows the very close agreement (99.59%) of the diagnostic microscopic slide precipitation tests with the non-cholesterinized Wassermann reaction in patients with no evidence of neurosyphilis. There is a relatively lower agreement in the proven neurosyphilitics. There were 31 disagreements, twenty-eight of

which were positive with the diagnostic microscopic slide precipitation test and negative with the Wassermann. Thus, if the diagnostic slide test alone had been done, only three cases of neurosyphilis would have been missed, while if the Wassermann test alone had been done, twenty-eight cases of neurosyphilis would have been missed. This shows the increased sensitivity of the diagnostic slide test over the non-cholesterinized Wassermann test, and the importance of doing both a precipitation test and a complement fixation test on all fluids in order to report the most accurate results to the clinician. There was one false positive in the diagnostic slide precipitation test occurring in a case of tuberculosis meningitis.

Table V shows the very close agreement (98.77%) of the exclusion microscopic slide precipitation test with the cholesterinized Wassermann in the non-neurosyphilitic cases. There were thirty-four disagreements in the proven neurosyphilitics, 31 of which were positive in the

slide test and negative in the cholesterinized Wassermann. This table shows the increased sensitivity of the exclusion slide test over the Wassermann reaction and that the Wassermann reaction alone, even with a sensitized antigen, is not adequate and should be supplemented by the more sensitive slide precipitation test.

Table VI shows the very close agreement of the diagnostic microscopic slide precipitation test with the albumin-globulin ratio. In the neurosyphilitic group there were fourteen disagreements, thirteen of which were positive with the slide test and negative with the total protein-globulin ratio. Thus, if the latter test alone would have been used, thirteen cases of neurosyphilis would have been missed, while if the diagnostic slide test would have been used alone, only one case of neurosyphilis would have been missed.

Table VII shows a similar close agreement of the exclusion microscopic slide precipitation test with the albumin-globulin ratio. This more sen-

studies will have to be carried out in this last patient before a definite conclusion can be made.

Table VIII shows the increase in sensitiveness of the diagnostic microscopic slide precipitation test over the Ishii modification of the Kahn test. Of twenty-nine fluids which gave strongly positive reactions with diagnostic slide test, ten gave similar reactions, six gave weakly positive reactions and thirteen gave doubtful reactions with the Kahn test. Of 9 fluids which gave weakly positive reactions with the diagnostic slide test,

2 gave similar reactions, 4 gave doubtful reactions and 3 were negative with the Kahn test. Of 5 fluids that gave doubtful reactions with the diagnostic slide test, 1 gave a similar reaction and 4 were negative with the Kahn test. Of 103 fluids that were negative with the diagnostic slide test, five gave doubtful reactions and 98 were negative with the Kahn test. This table also shows that the slide test gave 19.86 per cent four plus reactions as compared with 6.84 per cent with the Kahn test, or an increase in 13.02 per

cent. In the case of the weakly positive reactions the increase in sensitiveness was only 0.69 per cent.

Table IX. In order to facilitate the comparison of the colloidal gold and the diagnostic microscopic slide precipitation, the observations of the former were interpreted on a four plus basis. Thus, where one or more tubes showed complete precipitation the results were read as four plus (strongly positive), while when the precipitations were less complete, they were read as three plus and two plus (weakly positive), and one plus (doubtful). In this series there were 25 doubtful and 10 positive reactions in fluids from patients who were definitely non-neurosyphilitic. There were 55 doubtful reactions in spinal fluids of neurosyphilitic patients 44 of which gave doubtful or positive reactions with the microscopic slide precipitation tests. Of the 25 disagreements in the neurosyphilitic cases, 21 were positive with the slide test and negative with the colloidal gold. This shows that the diagnostic microscopic slide precipitation test is not only more sensitive, but also more specific than the colloidal gold reaction. The total agreement of the combined neurosyphilitic and non-neurosyphilitic groups was 92.61 per cent.

DISCUSSION

The various spinal fluid procedures are indispensable aids in diagnosis and are sometimes the sole means of detecting early asymptomatic neurosyphilis. In this series the microscopic slide precipitation test showed not only a high degree of sensitivity and specificity, but also gave immediate evidence as to the diagnosis and exclusion of neurosyphilis. In this comparative study, the slide test performed alone would have given more correct information than the combined Wassermann, Kahn and colloidal gold reactions.

The diagnostic test when definitely positive (two plus to four plus) may, with very rare exceptions, be relied upon as diagnostic of neurosyphilis. This test was considerably more sensitive and agreed more closely with the clinical findings of the patient than the Wassermann reaction with the non-cholesterinized antigen. The exclusion test was more sensitive than the diagnostic test and consequently there was a corresponding increase in sensitiveness of the former over the Wassermann reactions. Because of this increased sensitivity the exclusion test should play an important role in detecting the invasion of the central nervous system by the spirocheta pallida before the appearance of clinical symp-

toms or before the disease has had the opportunity of progressing to such a degree when treatment would be inadequate.

The exclusion test gave positive reactions when the other spinal fluid procedures were negative in a reasonable number of cases of old tabes, syphilitic ocular palsies and asymptomatic neurosyphilis.

With the exclusion test an occasional doubtful and positive reaction was obtained in syphilitic cases free from any clinical evidence of neurosyphilis. Such reactions should not be used for the diagnosis of neurosyphilis, but rather when negative, as indicating the absence of neurosyphilis. A positive exclusion test might, however, prove to be an indicator of very early involvement of the central nervous system, but considerable more study will have to be made for an extended period of time along these lines before any significant deductions can be made.

In cases of neurosyphilis under treatment, especially in the meningo-vascular type the Wassermann reactions, Kahn tests, colloidal gold reactions and albumin globulin ratios became negative before the microscopic slide precipitation tests, and therefore, when the latter became negative they had a greater value as to diagnosis and prognosis. Further study will be required to determine the amount and time of treatment necessary in such patients after slide tests become negative, but the amount of treatment will undoubtedly be much shorter than was necessary, when less sensitive spinal fluid tests were used.

The diagnostic slide precipitation tests were negative in a number of nonsyphilitic spinal fluids which gave positive colloidal gold reactions such

as multiple sclerosis, tumors and encephalitis. Doubtful and even positive colloidal gold reactions in the absence of clinical or other serological corroborative evidence must be interpreted with a great deal of caution.

CONCLUSIONS

1 The microscopic slide precipitation test with spinal fluids has been found to be more sensitive than the Wassermann reaction, modified Kahn test, colloidal gold reaction and albumin-globulin ratios.

2 This test gave results which agreed more frequently with the clinical condition of the patients than those of the other spinal fluid tests used in this series.

3 The test is simple in detail and the results magnified by the microscope are read accurately with ease.

CISTERNAL PUNCTURE*

By MORRIS A. LYONS, M.D., NEW YORK, N. Y.

From the Department of Dermatology and Syphilology of the New York Post-Graduate Medical School and Hospital, Dr. G. M. Mackee,
Director; Service of Dr. I. Rosen, Professor of Dermatology and Syphilology.

QUINSKE¹ in 1890 was the first to suggest the possibility of entering the cisterna magna to obtain cerebrospinal fluid. He considered the procedure too dangerous and abandoned it in favor of lumbar puncture which he originated and believed to be safe. Ayres² and Eskuchen³ however devised the present methods of performing cistern puncture. Westenhoeffer⁴ in 1905 cut a window in the atlanto-occipital membrane for drainage purposes while Obregia⁵ claims to have done a suboccipital rachicentesis in 1908. In 1913 Dixon and Halliburton⁶ demonstrated that cerebrospinal fluid could be successfully obtained from the cerebral reservoirs by direct puncture through the occipito-atlantoid ligament of a dog and this technic was extensively used by them and Weed⁷ in 1914. Chartier⁸ performed a spinal puncture at the level of the 8th dorsal interspace and obtained spinal fluid in two instances, while Revaut and Krolunitzky⁹ obtained fluid by puncture at the 7th interspace. Netter¹⁰ in 1916 successfully used both lumbar and suboccipital routes. Canzaman¹¹ in 1916 obtained cerebrospinal fluid via the sphenoidal route, as did Berriel¹² by inserting a needle from in front and below the eye. Purves-Stewart¹³ obtained cerebrospinal fluid by entering the cavum Meckelii through the foramen ovale in 1925. Herrick,¹³ Cushing and Sladen,¹⁴ Ambertin and Chabanier,¹⁵ Capitan,¹⁶ Franco,¹⁷ and Miller¹⁸ very early used cistern puncture alone or together with lumbar puncture in cerebrospinal infections.

Ayres performed numerous cistern punctures on the cat prior to 1919 with only 10 injuries to the medulla. He thought the method could be successfully used on the human which he described together with Essick and Wegforth in 1919. This method is frequently called the "Direct Method." The needle is inserted just above the spine of the axis in the median line in the back of the neck. The upper edge of the external auditory meatus and the glabella are valuable guides for directing the forward stroke of the cistern puncture needle, for a plane passed through them and the point of insertion on the back of the neck will pass through the occipito-atlantoid ligament. The depth of cisterns varies with the individual and on cadavers (2) the average was 4 c.m., rarely 5 c.m. or less than 3 c.m. from the skin surface. The stylette remains in the needle to the very end of the procedure and tactile impression alone or "give" is the only guide the operator has upon passing through the

ligament and dura. Ayres also remarks that the head could be moved in any direction without altering the position of the needle to the nerve structures; an important thing to know when puncturing unruly patients. Not more than 5 c.m. depth from the skin surface is advised. That the stylette remains in the needle to the end of the puncture and tactile sense alone is relied upon removes an important safety factor when the "give" is hard to note; besides some cisterns are more than 5 c.m. deep.

Eskuchen in 1923 published his description of a new technic for cistern puncture, known as the "Indirect Method." It is essentially accomplished in two stages. The point for the insertion of the needle is selected by passing the index finger of the left hand down the back of the head and neck, starting at the posterior occipital protuberance, until it enters the hollow just above the tip of the second cervical vertebra. With the index finger still in this position, the needle is inserted in the median line of the head to the occiput at an angle. The stylette is then withdrawn and by upward pressure on the shank of the needle and by pushing the needle forward very slowly, the cisterna magna is entered. Cerebrospinal fluid can be seen dropping from the free end of the needle at this stage. The object in the second stage is to follow the under surface of the occipital bone very closely. The exact angle at which the first stroke is made is not given clearly by Eskuchen but it is advised to reach the bone too soon rather than miss it altogether, for in the later event the cistern may be entered directly. It is essential in order to perform the Eskuchen method to reach the occiput. Sometimes puncture of the skin meets with difficulty and in such cases a quick stroke through it at a right angle is advisable. The needle with this technic should enter the cistern at the posterior rim of the foramen magnum and it is at this point that the occipito-atlantoid ligament and meninges are penetrated with at times the feeling of a "give." Too great pressure at this stage should be avoided in order not to "overpass." In the second stage the cistern may be reached in either a few m.m. to 1.5 c.m., more than this distance should be carried out very cautiously.

Roentgenographic studies of every step in the performance of cistern puncture clearly shows that the point of the needle enters the cranial cavity through the foramen magnum and that this point is more superficial than is generally believed. It is therefore a procedure where the greatest caution must be exercised in technic and asepsis. Of 679 cistern punctures performed

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 2, 1931.

nearly all were reached within 3.5 c.m. to 5 c.m. from the skin surface, only a few were 6 c.m. to 7 c.m. deep and one 7.5 c.m.

The space through which the cistern puncture is performed is triangular in shape. The apex is in the fossa subcerebellaris magna and the base on the skin of the neck. The upper boundary is made up of the posterior occipital protuberance and the crest on the under surface of the occipital bone. The inferior boundary is the upper surface of the spine of the axis and the posterior and upper part of the rudimentary spinous process of the posterior arch of the atlas. The lateral walls of this triangular space are made up of the trapezius, complexus and rectus capitus posticus minor muscles (19;20). The base is the skin on the back of the neck between the posterior occipital protuberance and the tip of the spine of the second cervical vertebra. The structures penetrated by the needle are skin, cervical fascia, ligamentum nucae, loose connective tissue, occipito-atlantoid ligament and meninges. Such important structures as the vertebral arteries, posterior occipital nerves and lower end of the medulla are in the vicinity of the end of the cistern puncture needle. The space between the meninges and the brain structures at this point is estimated as from 0.5 c.m. to 1.5 c.m. (12). The space through which the cistern puncture needle passes between the atlas and the posterior rim of the foramen magnum of the occipital bone as seen on a wet specimen of a sagittal section of the head and neck was 3 m.m. With flexion of the head on the living subject this may appear greater as shown on x-ray examination of a thin patient as being 7 m.m. on the film, which with the factors used in taking the film would give an actual distance in this patient of nearly 2 m.m.

A modification of the existing technics together with a general improvement in asepsis not only aids in the performance of cistern puncture but insures the patient against possible infection. The patient is placed on his right side and shoulder with his head on a block of wood in such a manner that the sagittal plane of the head, cervical vertebrae and dorsal vertebrae are on a horizontal plane and at right angles to a plane through the spines of the scapulae. The head is then flexed so that the chin rests on the chest. The point for cistern puncture is then palpated and a dime sized tuft of hair removed. The back of the head and neck is thoroughly washed with first alcohol, then iodine and again alcohol. A sterile cap, triangular in shape with a window the size of a silver dollar cut in the center of the long side, is adjusted to the head so that only the suboccipital depression is exposed. The shoulders and surrounding field are covered with sterile sheet and towels and the operator besides wearing a short operating room coat, wears sterile gloves. The cistern puncture needles are sterilized in glass

tubes and done up twelve to a package. With the gloved index finger of the left hand held firmly over the tip of the spine of the axis, the cistern puncture needle is inserted in the center of the hollow just above the second cervical vertebra and below the posterior occipital protuberance, for 2.5 c.m. in the median sagittal plane of the head, with the needle point directed one inch above the glabella. No attempt is made to reach the occiput. The stillette is then withdrawn and by slightly raising the handle of the needle so that the point is just below the glabella, very slow pressure is applied to the needle which enters the cisterna magna very readily. Cerebrospinal fluid immediately escapes from the free end of the needle at this stage and the procedure is completed. The index finger of the left hand can be removed after the stillette is removed. With the collection of the spinal fluid completed, the needle is quickly withdrawn, the puncture hole painted with collodion and a small piece of sterile gauze pressed firmly against it. The patient may then get up and leave.

One of the great assets of cistern puncture is the almost total absence of headache. Probably not more than once in one hundred cases does this happen. In one instance this persisted for two days but in the few other cases for only an hour or two. This headache when it occurs is prompt in its onset upon the sitting up of the patient after the cistern puncture and is referred to the frontal region. Drinking of water and lowering the head between the knees frequently relieves it. This of course is in marked contrast to lumbar puncture headache which is much more frequent and severe. The cerebrospinal fluid (19;20;21) obtained by cistern puncture from the fossa subcerebellaris magna is in direct communication above with the fourth ventricle through the foramen of Majendie and below with the central canal of the spinal cord. From the lateral ventricles the fluid enters the third ventricle through the foramen of Monro and thence the fourth ventricle through the aqueduct of Sylvius. By way of the lateral recesses and the foramen of Luschka, the cerebrospinal fluid enters the subarachnoid space. To a great measure the fluid is absorbed into the venous circulation through the Pacchionian bodies. Because of the intimate relationship of the fluid within the fossa subcerebellaris magna and the fourth ventricle through the large foramen of Majendie, changes in the amount of fluid as a result of cistern puncture are referred to the intraventricular system or reservoir. The subarachnoid space retains its spinal fluid cushion for the brain and headache is avoided.

Studies on the quantity of cerebrospinal fluid were made by Mestrezat and Frazier²² who estimated that the fluid renews itself six to seven times in 24 hours, the average amount of change

being 125 c.c. to 175 c.c. so that about 1000 c.c. were formed in 24 hours. The rate of flow from the Sylvian fissure of two dogs²³ was 0.231 c.c. to 0.192 c.c. Reese²⁴ demonstrated that in normal fluid the cell count, globulin and Wassermann reactions were the same whereas in pathological fluids, that obtained by lumbar puncture was more strongly positive in cells, globulin and Wassermann reaction. A later study on a greater series of cases²⁵ by Saunders showed that the colloidal gold and Wassermann reactions were the same in both specimens but that cells and globulin were found in greater amounts in the fluid obtained by lumbar puncture. Kubie²⁶ speaks of the rise in the protein content of the spinal fluid following glucose injections while following the intravenous injection of hypotonic saline solution, the flow of cerebrospinal fluid is renewed with a still greater percentage of lymphocytes, after it has almost ceased.

The amount of cerebrospinal fluid that can be withdrawn without any bad effects upon the patient varies. Ebaugh²⁷ removed 60 c.c. to 80 c.c. by cistern puncture followed immediately by intravenous hypertonic saline, without any bad effects on the patient. In one patient where 40 c.c. of fluid were removed, the patient had severe chills, headache, pallor and a weak and rapid pulse. After stimulants by mouth were given, the patient was able to leave but remained in bed for 24 hours. Parasthesia of the right hand, which persisted for several days was noted in an outside case. Pfister²⁸ had one case where artificial respiration had to be done for several hours, following cistern puncture. A case of death is reported due to an abnormal cerebellar artery²⁹. In a collection of 10000 cistern punctures³⁰ there were only 7 bad results reported. Of 679 cistern punctures performed at this clinic, no mishap occurred except for four headaches and weakness in the right leg of one patient which cleared up in an hour. Death occurred in one case of cranial hemorrhage and another of meningitis following cistern puncture at another hospital. In view of the many thousands of cistern punctures being performed, greater care must be urged upon those in this work especially the beginners.

Cistern puncture possesses certain advantages over lumbar puncture. These are the ease with which cerebrospinal fluid can be obtained for diagnosis, lack of headache and its therapeutic applications. So simple is it to obtain cerebrospinal fluid for diagnosis, after the technic is acquired, that the procedure becomes an office or out-patient clinic operation. For the syphilologist it is an easy means not only for diagnosing syphilitic involvement of the cerebrospinal axis, but it is also an easy method for obtaining fluid for serological tests as a guide in the treatment where syphilis involves the central nervous

system. Before discharging a treated syphilitic patient this route serves as an excellent means of obtaining cerebrospinal fluid.

The intracisternal treatment of optic atrophy due to syphilis has been described by Gifford,³¹ Viner and McMurtry,³² Gifford and Keegan,³³ Gifford³⁴ and Hume.³⁵ Marie and Leri³⁶ concluded that the first lesion in the nerve is an endovascularitis of tertiary syphilis causing secondary atrophy; a conclusion also reached by Staigart. Paton believes that the toxic theory should be abandoned, while Igersheimer found spirocheta near the optic nerve but not in it. Sucker replaced salvarsan by mercury. The procedure was to allow ten drops of a solution containing one-fiftieth of a grain of bichloride of mercury to gravitate into the fossa subcerebellaris magna by way of cistern puncture, after ten cubic centimeters of cerebrospinal fluid was removed. The conclusions reached by Gifford with the intracisternal injections of mercury bichloride in syphilitic optic atrophy were that these injections have given better results than any other method; that intracisternal injections are relatively simple to do; that improvement in vision is evidence of an active infiltrative lesion; that the best results are obtained in early cases with definite defects in part of the field of vision and relatively good vision in one eye and little evidence of other nervous involvement. The reactions following this treatment were at times severe.

The suboccipital route has been used extensively in the treatment of paresis, tabes dorsalis and cerebrospinal syphilis. Ebaugh²⁷ mentions Berriel as having injected arsphenamized serum by way of the sphenoidal route and also credits McKusker for having published the first case. The arsphenamized serum was prepared in the regular manner with the addition of 0.5 to 1.0 milligram of arsphenamine and diluted to 25 c.c. with saline. The same amount of arsphenamized serum was introduced as spinal fluid drained via the suboccipital route. Following this procedure, 50 c.c. of saline was injected intravenously, to encourage an increase in the flow of cerebrospinal fluid. Tryparsphenamized serum prepared in a similar manner was also used. Besides Ebaugh, Edge,³⁸ Stewart³⁹ and others have worked along this line and while theoretically a good method, yet their results were discouraging in the advanced paretics they treated. Drainage following the intravenous injection of salvarsan, silver salvarsan and tryarsamide has been more encouraging in neurosyphilis. In a general way the procedure was to do a suboccipital drainage in 20 to 30 minutes following the intravenous injection. The amount of cerebrospinal fluid removed varied from 15 c.c. to 35 c.c. From six to eight intravenous injections at weekly intervals was considered a course with a rest intervening of from three to four weeks.

Bleeding causing contaminated cerebrospinal fluid is more frequent with cistern puncture than with lumbar puncture in the hands of the same operator. From 2 to 3 percent of such cases is a fair estimate. It seems that the short bevel of the cistern puncture needle pushes the meninges ahead of it in these bleeding cases, causing a small lacuna of venous blood to form. Withdrawing the needle and performing another cistern puncture by a different method frequently results in clear fluid. No bad effects have been noted even in those cases where the cerebrospinal fluid was blood tinged.

CONCLUSIONS

1. Cisterna puncture is performed through a definite anatomical space.
2. The modified technic is simple to do and safe.
3. The almost total lack of headache is a great advantage in cistern puncture over lumbar puncture.
4. Cistern puncture has been a great aid in the diagnosis and treatment of intra-cranial infections.
5. Serious injuries following cistern puncture are rare.

RECORDED AND RESIDENT DEATH RATES IN NEW YORK STATE

By J. V. DE PORTE, Ph.D., ALBANY, N. Y.

Director, Division of Vital Statistics, New York State Department of Health.

NO. I—ALL CAUSES, 1926-1930

THE generally accepted measure of the risk of death in a given period of time and in a given place is the fraction obtained by dividing the number of deaths in that place during the stated time by the number of people residing there. Thus, if one states that the death rate in the State of New York in 1930 was 11.7 per 1,000 population, it means that the risk of the "average" person dying in the State in 1930 was as 11.7 is to 1,000 or about 1 in 85. If one were to define the "average" person within certain ages or limit him to one racial group or occupation, the risk of death would be expressed by relating the number of deaths occurring in the group to which the "average" person is now confined to the number of persons in that smaller population. In addition to the total death rates, based on mortality from all causes in the entire population, there are, therefore, specific death rates by sex, age, cause of death, occupation, etc.

The rate of mortality would be a precise measure of the risk of death provided the numbers upon which it is based were exact. It is, however, generally recognized that these numbers are, inevitably, open to a certain degree of error. The populations employed in the computation of annual rates are estimated as of July 1 of each year. The accuracy of these estimates depends directly upon the size of the population and the interval of time separating the period considered from the last census. Also, even with a perfectly functioning system of registration, the total number of deaths ascribed to a certain cause does not necessarily represent the true mortality from this cause. Accuracy of diagnosis is one factor of importance; another is the fact that a disease may be contracted in one place and the death occur in a different place. The Public Health Law of this State provides that a death must be recorded in the city, town, or village in which it occurs. The official death rate, based on the number of deaths occurring in each administrative unit, therefore, frequently underestimates or overestimates the actual volume of mortality among the population. In 1926 the Division of Vital Statistics of the State Department of Health commenced to allocate deaths according to the residence of the decedent or the place in which the disease leading to death was known to be contracted or the fatal injury sustained.

The present article deals with recorded and corrected death rates from all causes. It will be followed by a similar presentation of the death

rates from tuberculosis and cancer and of infant mortality and maternal mortality. The table below shows the death rates from all causes per 1,000 population, recorded and corrected for residence, in New York City and in the urban and rural up-State territories in 1926-1930:

Year	New York City Re- corded	New York City Resi- dent	Rest of State Re- corded	Rest of State Resi- dent	Urban Re- corded	Urban Resi- dent	Rural Re- corded	Rural Resi- dent
1926	11.8	12.0	14.0	13.8	13.8	13.5	13.0	14.4
1927	10.7	10.9	13.0	12.7	12.6	12.3	12.3	13.7
1928	11.6	11.9	13.3	13.0	13.2	12.7	12.3	13.9
1929	11.3	11.6	13.7	13.4	13.4	12.9	12.8	14.6
1930	10.8	11.0	12.8	12.5	12.5	11.9	12.1	13.8

Main Divisions of the State: In 1930 the resident death rate of New York City was higher than the recorded rate by 0.2 while up-State the resident rate was lower than the recorded figure by 0.3. The rate of the urban up-State territory is reduced from 12.5 to 11.9; the rate of rural New York is increased from 12.1 to 13.8. Thus, while the *recorded* death rate of urban up-State was 3 per cent higher than the rural rate, the *resident* urban rate is 14 per cent lower than the resident rural rate.

Cities: The resident death rates of most of the cities were less than the recorded rates. Below are listed cities over 25,000 population whose resident rates in 1930 were less than the recorded figures by 10 per cent or more:

	Recorded	Resident
Albany	14.8	13.1
Amsterdam	12.2	10.4
Auburn	14.6	12.5
Elmira	16.8	14.4
Jamestown	12.0	9.8
Kingston	21.5	16.1
Newburgh	16.7	14.3
Rome	16.6	13.3
Watertown	17.2	13.4

Rural Area of Counties: The resident death rates of the rural areas of counties were higher than the recorded rates with the following exceptions:

	Recorded	Resident
Dutchess	16.9	14.7
Franklin	16.0	14.2
Seneca	12.2	11.1
Westchester	12.2	9.4

NEW YORK STATE JOURNAL OF MEDICINE

Published semi-monthly by the Medical Society of the State of New York under the auspices of the Committee on Publication.

CHARLES H. GOODRICH, M.D., *Chairman*.....Brooklyn CHAS. GORDON HEYD, M.D.,.....New York
DANIEL S. DOUGHERTY, M.D.,.....New York

Editor-in-Chief—ORRIN SAGE WIGHTMAN, M.D.,.....New York *Executive Editor*—FRANK OVERTON, M.D.,.....Patchogue

The Medical Society of the State of New York is not responsible for views or statements, outside of its own authoritative actions, published in the JOURNAL. Views expressed in the various departments of the JOURNAL represent the views of the writers.

MEDICAL SOCIETY OF THE STATE OF NEW YORK

Offices at 2 East 103rd Street, New York City. Telephone ATwater 9-7524

OFFICERS

President—WILLIAM D. JOHNSON, M.D.,.....Albany
First Vice-President—CHARLES C. BROWN, M.D.,.....New York
Secretary—DANIEL S. DOUGHERTY, M.D.,.....New York
Treasurer—FREDERIC E. SONDERM, M.D.,.....New York
Speaker—JOHN A. CARD, M.D.,.....Longueville
President Elect—CHAS. GORDON HEYD, M.D.,.....New York
Second Vice-President—HARRISON, M.D.,.....New York
Assistant Secretary—PETER IRVING, M.D.,.....New York
Assistant Treasurer—JAMES PEDERSEN, M.D.,.....New York
Vice-Speaker—GEORGE W. COTTIS, M.D.,.....Jamestown

TRUSTEES

JAMES F. ROONEY, M.D., *Chairman*,.....Albany
ARTHUR W. BOOTH, M.D.,.....Elmira
NATHAN B. VAN ETTEN, M.D.,.....New York
HARRY R. TRICK, M.D.,.....Buffalo

CHAIRMAN, STANDING COMMITTEES

Arrangements—HERBERT A. SMITH, M.D.,.....Buffalo
Legislative—HARRY ARANOW, M.D.,.....New York
Pub. Health and Med. Education—T. P. FARMER, M.D., Syracuse
Scientific Work—ARTHUR J. BEDELL, M.D.,.....Albany
Medical Economics—CHARLES H. GOODRICH, M.D.,.....Brooklyn
Public Relations—JAMES E. SADLER, M.D.,.....Poughkeepsie
Medical Research—STANHOPE BAYNE-JONES, M.D.,.....Rochester

CHAIRMEN, SPECIAL COMMITTEES

Group Insurance—JOHN A. CARD, M.D.,.....Longueville
Periodic Health Exam's—C. WARD, M.D.,.....New York
Nurse Problem—NATHAN B. VAN ETTEN, M.D.,.....Buffalo
Physical Therapy—RICHARD KOVACS, M.D.,.....New York
Prize Essays—EDWIN MACD. STANTON, M.D.,.....Schenectady

PRESIDENTS, DISTRICT BRANCHES

First District—CHARLES D. KESNE, M.D.,.....Nyack
Second District—LOUIS A. VAN KLEECK, M.D.,.....Manhasset
Third District—HERBERT L. ODELL, M.D.,.....Sharon Springs
Fourth District—FRANK VANDER BOGERT, M.D.,.....Schenectady
Fifth District—AUGUSTUS B. SANTRY, M.D.,.....Little Falls
Sixth District—GEORGE M. CADY, M.D.,.....Bronx
Seventh District—E. ROSS THOMPSON, M.D.,.....Penn Yan
Eighth District—W. ROSS THOMPSON, M.D.,.....Warsaw

SECTION OFFICERS

Medicine—DAVID A. HALLER, M.D., *Chairman*, Rochester; EDWARD C. REIFENSTEIN, M.D., *Secretary*, Syracuse.
Surgery—ARTHUR M. WRIGHT, M.D., *Chairman*, New York; EDWARD R. CUNIFFE, M.D., *Secretary*, Bronx.
Obstetrics and Gynecology—GEORGE H. BONNEYTON, M.D., *Chairman*, Utica; EDWARD C. HUGHES, M.D., *Secretary*, Syracuse.
Pediatrics—ALBERT D. KAISER, M.D., *Chairman*, Rochester; BREWSTER C. DOUST, M.D., *Vice-Chairman*, Syracuse; ADOLPH G. DE-SANCTIS, M.D., *Secretary*, New York.
Eye, Ear, Nose and Throat—RICHARD T. ATKINS, M.D., *Chairman*, New York; DAVID F. GILLETTE, M.D., *Secretary*, Syracuse.
Public Health, Hygiene and Sanitation—FRANK W. LAIDLAW, M.D., *Chairman*, Middletown; DANIEL R. REILLY, M.D., *Secretary*, Cortland.
Neurology and Psychiatry—IRVING J. SANDS, M.D., *Chairman*, Brooklyn; HENRY W. WILLIAMS, M.D., *Secretary*, Rochester.
Dermatology and Syphilology—EDWARD R. MALONEY, M.D., *Chairman*, New York; GEORGE C. ANDREWS, M.D., *Secretary*, New York.

LEGAL

Office at 15 Park Place, New York. Telephone, BARELEY 7-5550

Counsel—LORENZ J. BROSNAN, Esq.

Executive Officer—JOSEPH S. LAWRENCE, M.D., 100 State St., Albany. Telephone, Main 4-4214.

For list of officers of County Medical Societies, see this issue, advertising page xxx.

Annual meeting, Hotel Statler, Buffalo, N. Y., May 23-25, 1932

THE OUTLOOK

The year 1932 opens auspiciously for the Medical Society of the State of New York and its constituent County Societies. The most encouraging omen of the new year is the number of objectives which the members are seeking to reach. Physicians always respond when there is something to be done, or a needed policy is to be popularized. The older activities in public health and graduate education will be continued more vigorously than ever; while the public relations of practicing

physicians will be extended as a result of the studies of the Governor's Health Commission. The Medical Societies are also entering the new field of medical publicity, and are seeking practical ways of informing the people how they may secure the benefits of scientific medicine. There is every indication that the medical societies will assert a controlling influence in the development of the policies of the civil authorities in their administration of health matters.

A MEDICAL MUSEUM

The vision of a central medical museum under the auspices of the New York Academy of Medicine was suggested by Dr. Linsly R. Williams at the annual meeting of the Academy on January seventh. That the idea is both practical and popular is shown by the amount of space given to it on the following day by the New York newspapers.

New York is a great center of everything that is progressive and modern. It has more centers than one realizes, unless he stops to enumerate them. Its reputation as the center of the world's business and finance is so great that it is often said that money submerges all other features of the city. But where great wealth is centered, there the humanities also flourish under the patronage of those having the financial means to indulge their avocations. Men who build great business enterprises are successful to the degree that they supply widespread needs of mankind. When a man has accumulated wealth far beyond his own needs, he naturally makes provision that the public may share in the culture in which he finds gratification. If he is musical, he endows a music center; if he delights in art, he gives his collections as the nucleus of an art gallery; or if science appeals to him, he establishes a museum of natural history or endows a university foundation for teaching and research. It is but natural that New York, the financial center of the world, should support the American Museum of Natural History, the Metropolitan Museum of Art, the Botanical Garden, and great universities, all established for the benefit of mankind generally.

New York also has its medical centers. The Rockefeller Institute for Medical Research seeks to develop newer and more exact means of diagnosis and treatment which the family physician can apply in his practice. Columbia University has developed its College of Physicians and Surgeons into a medical center in which undergraduate teaching, hospital service, and scientific research are combined in one group of buildings; and other universities are developing similar plans.

The New York Academy of Medicine is another great medical center; and its membership is composed of leading practitioners in all branches of medicine. Its meetings have been forums for the discussion of medical problems of a civic nature as well as those applying to sick individuals. The Academy is a powerful force in influencing the action of civic bodies in adopting measures relating to health.

One of the greatest activities of the Academy has been the development of a Medical Library, which ranks second only to the Library of the Surgeon General in Washington. The Library

of the Academy contains the germs of a great medical museum whose influence shall appeal to the people generally as well as physicians. Already the Library is open to the public at certain hours and is used by research workers, especially those interested in the broader phases of medical history.

An essential element in the development of the Library into a public museum will be the preparation of indexes and bibliographies so complete that untrained readers may readily find the reference to any medical subject that they may wish to investigate.

There will also be needed a staff of trained librarians who will be familiar with the literature of medicine, and will be ready to assist readers to find information on all subjects.

The popular conception of a museum is that it is a collection of specimens of a spectacular nature. A medical museum will never appeal to the sightseeing visitor; but yet it will contain models and charts which will explain the living action of the body according to the laws of chemistry and physics. There will be models of the heart pump, and of the chemical factory of a gland, and the propagation and transmission of nerve impulses. To dispel the mystery of living action within the body is the first step in combating the influence of the quack and the cultist.

The medical museum will also enter the great field of sanitation and its relation to health. The successive steps of the development of sanitation of New York City are still being repeated over and over everywhere as new towns develop. The camper and the lone farmer practice the sanitation of the New York City of one hundred years ago. The country village that installs a water system follows the example of New York when it introduced croton water in 1842; and the householder who builds a cesspool is somewhat in advance of the New York City of today which has not yet provided the up-to-date sewage disposal system for its people. The medical museum will visualize unsanitary conditions and the measures for improving them.

There is no museum anywhere that is to medicine what the American Museum of Natural History is to biology and its subdivisions such as zoology, ornithology, paleontology, and anthropology—and there never will be until other physicians join Doctor Williams in presenting the vision of a medical center to which the people may turn for information and inspiration, just as they now look to the American Museum of Natural History and the Metropolitan Museum of Art. When physicians include a medical museum among their major plans for the future, the business men of New York City will provide the funds for its establishment.

MEDICAL LEGISLATION

Since the Legislature of the State of New York is in session, the usual run of medical bills may be expected. On the one hand are bills sanctioned by governmental officials and lay health organizations dealing with administrative machinery by which the community may do its duty to people who are sick or are threatened with illness. This class of bills includes those sanctioned by Governor Roosevelt's Health Commission. The Medical profession approves the principles of these bills, although some change of details may be proposed as a result of the deliberations of the House of Delegates.

In contrast to the medical bills introduced by experienced administrators are those proposed by cultists and quacks asking for special privileges for ignorant healers. The arguments for these bills consist of testimonials from the minority of persons who say they feel better after having taken the treatments. Modern advertising is based on testimonies. If the wife of a man prominent in business or the government advertises her confidence in a preparation used on the skin or in the kitchen, other women buy that article even though half a dozen rival articles are advertised in a similar way in the same magazine.

A person goes to a cultist or a quack because some friend or neighbor says that he was helped by the healer. A legislator supports cult bills because he hears the testimony of his neighbors that they have received benefit from the cultists after the doctors had given them up. Such testimony is hard to refute for what a person sees or experiences is accepted in a

law court as of greater weight than the opinions of doctors who have not seen the case.

Cultists seek to give the impression that they are successful with the great majority of cases which they treat. A legislator gets this impression when he receives testimonial letters from a dozen patrons of a cultist in his district. If a doctor were to combat this evidence in a law court, he would have to produce over one hundred witnesses to testify that they had not received benefit and so to prove that improvement follows the alleged treatment in only a small proportion of the cases. The cultist evidently has the best of an argument based on the witness of ordinary citizens.

The influence of personal contacts is greater than that of reason. The legislator is naturally biased in favor of the doctor, and he values the evidence of the patients of the physician far higher than that of the patrons of the cultist. Who can estimate the value of a number of letters from prominent citizens asking a legislator to oppose the granting of special privileges to cultists? The present medical practice act was passed because doctors influenced their prominent patients to write to their legislators and ask them to support the bill.

The doctor will be successful in legislation when he heeds the example of the cultist and induces his patients to state their wishes to their legislators. Effective machinery for doing this is provided by the Tuberculosis and Public Health Associations of the counties.

LOOKING BACKWARD

This Journal Twenty-five Years Ago

First Year of Amalgamated State Society The year 1907 was the second year of the amalgamation of the former State Society with its rival, the State Association. What the amalgamation did for New York County in the first year is told in an article in this Journal for January, 1907. The President, Dr. Floyd M. Crandall, summarized the results as follows:

"To summarize the inquiry regarding the effect of amalgamation upon the Medical Society of the County of New York we find 1 That the receipts from membership dues the first fiscal year after amalgamation were \$2,189 greater than the average receipts for the five years preceding it, and \$1,803 greater than for the year immediately preceding it.

"2 That 68 per cent of the membership was in

arrears of dues on December 31, 1906, as compared with 21 per cent in arrears at the end of the year preceding amalgamation.

"3 That 2,178 members paid dues for the first year after amalgamation as compared with 1,476 for the year immediately preceding it, that is 702 more members paid dues in 1906 than in 1905.

"4 That this increase of 702 was but partially due to the members received from the Association of whom 387 paid their dues.

"5 That prior to 1906, the total paid membership never reached 1,500.

"In New York County, therefore, union and the new system of organization have brought a larger membership and greater income than ever before, and the percentage of members who have paid their dues has been unprecedented."

MEDICAL PROGRESS

The Three Phases of Hypertensive Disease.

—Chronic progressive hypertension should be considered, says A. Dumas, not so much a symptom as a veritable disease. While its original cause is still little known, it appears to consist in humoral troubles which place it in the class of diatheses. Thus understood, hypertensive disease passes through three successive phases, which may be termed (1) solitary or functional, (2) organic, with visceral lesions, and (3) involutive or declining hypertension. Each of these has its own characteristic symptoms and lesions, and its own special complications, each requiring its own treatment. Owing to the long time covered by the evolution of the disease, each of these phases has been mistaken for a different affection. Thus we have seen described the hypertension of chronic nephritis, or hypertensive nephritis, which proves to be only the second phase of the general hypertensive disease, the organic or cardiorenal phase. More recently a solitary hypertension has been recognized which is in reality only the initial phase of all hypertension, while the third stage has long been described under the name of arteriosclerosis. The hypertensive disease is essentially hereditary, the antecedents of the subject having been diabetic, gouty, or arthritic individuals, suffering with an unbalanced humoral condition which all shared alike, whatever the particular manifestation. The nature of these humoral imbalances is not yet well understood. Treatment produces its best results in the first phase, provided the presence of hypertension has been recognized, which is not always the case, since the beginnings are insidious and objective symptoms few. It should consist of appropriate regimens, such as iodated medication, insulin, angioxyl, oxycyanide of mercury, together with a rest-cure, thermal baths, and the like. This phase may begin around the age of 40, and pass insensibly into the second stage, perhaps after a number of years. The second phase is better known, and here treatment is most frequently ineffective. Its complications are cerebral hemorrhage, pulmonary edema due to insufficiency of the left ventricle, heart block, or acute asystole, by reason of which many subjects do not reach the third or involutive stage, in which hypertension may give place to hypotension, with arterial cachexia and a state of progressive depression no longer calling for hypertensive remedies.—*Journal de médecine de Lyon*, September 20, 1931.

The Action of Iodine in Experimental Arteriosclerosis.—With a view to determine the

value of iodine in arteriosclerosis, Hans Liebig produced arteriosclerotic lesions in rabbits by administering a mixture of cholesterol and linseed oil. To some of them he administered contemporaneously a preparation consisting of iodine and a fatty acid, which appeared particularly well adapted for the purpose, because it circulates a long time in the blood and thus has opportunity to exert a particular influence upon the vessels. Lesions developed in 100 per cent of the control animals, chiefly in the aorta but also in arteries of medium caliber. The first doses of the iodine preparation were too weak to have any effect, and no difference was observed between the experimental animals and the controls. In later series of animals strong doses amounting to 50-100 mg. iodine per day per kilo body weight could be reached without ill effect, although these would have been lethal but for the special form of the preparation. In 75 per cent of the 28 animals used for the experiment, no lesions were produced in the aorta, or only lesions of little importance, notwithstanding the rabbits had been fed with cholesterol 1 gm. daily for 6 or 7 months and in some cases 11 months. Complete success may be expected only when the iodine treatment is begun very early and followed up without interruption. Care must also be taken that the amount of iodine reaches a certain high level. It is still impossible to say to what extent the experimental results can be applied to human beings. Nor can a definite interpretation be made of the mode in which the iodine acts upon the arteriosclerosis. Two possibilities present themselves to the mind: that of a direct action upon the vessel wall, and that of a general favorable effect upon the metabolism. It is probable that smaller doses of iodine than those administered would have been sufficient, such as could be prescribed for an arteriosclerotic without fear of injury.—*Riforma medica*, September 14, 1931.

The Physiology of Painful Sensation.—In discussing the nature and distribution of the pains that may result from injuries to the nerve-fibers of the sensory pathway, C. P. Symonds selects examples from different levels. In causalgia which may follow injury to one of the peripheral nerves there are three phenomena—spontaneous pain referred diffusely to the whole distribution of the nerve instead of to the spot stimulated, a raised threshold for all forms of cutaneous sensibility, and painful over-reaction to such stimuli as are able to cross the threshold. Analogous phenomena are observed in tabes in which the lesion is of the posterior roots, prob-

ably at their point of entry into the spinal cord, and also in lesions of the spinal cord and brain stem. As we get near the optic thalamus this syndrome is found most constantly and in the most marked degree. Clinical observation indicates that the essential condition for the production of this syndrome, at whatever level, is a certain degree of incompleteness of the lesion. The necessary degree of incompleteness may develop ab initio, or it may be attained only at a certain stage of recovery. In the case of a progressive lesion, the syndrome may appear and later disappear as the lesion becomes more severe, for example, in advancing degeneration of the posterior root-fibers in tabes. Occasionally the lesion may become stable at the essential degree of incompleteness and the syndrome persist indefinitely. These clinical observations are consistent with the hypothesis, originally suggested by Trotter and Davies, that the phenomena of raised threshold and over-reaction observed in the skin supplied by a regenerating nerve are due to a certain pathological state in the nerve-fibers themselves. Further support for this hypothesis is afforded by the finding of Adrian and his collaborators that the action of electric currents in afferent nerves behaves on the whole in very much the same way as in the efferent fibers. He found that the main feature of the stimulus which causes pain in the intact animal must be of relatively long duration, that is, it must possess a certain massiveness. Adrian also found that freeing the nerve from surrounding tissues, cutting, etc., caused spinal reflex movements in the animal and would be likely to cause pain in man. These findings suggest that the pain and painful over-reaction resulting from a partial lesion of the sensory fibers may be due to loss of insulation and consequent contact of naked axis cylinders with surrounding connective tissue.—*The Lancet*, October 3, 1931, ccxi, 5640

The Surgical Treatment of Angina Pectoris

—In view of the uncertainty as to the pathogenesis of angina pectoris, it seems rational, says Gino Pieri, to consider the problem of its treatment as one of the aspects of the surgery of pain in other words, to treat the symptom of pain by interrupting the afferent sensory tracts of the cardio aortic plexus. In carrying out this method, it seemed wise to avoid, so far as possible, the destruction of the sympathetic ganglia of the ltero vertebral chain, since their function, probably a trophic one, is not definitely known, and to sacrifice them, especially the stellate ganglion, might do incalculable injury. In a case described in which he adopted this conservative principle, he sectioned (1) all the rami communicantes that are directed outward from the stellate ganglion and from the ganglion intermediale above it, (2) the cord of the sympathetic near the lower pole of the ganglion superius, (3) a bun-

dle of nerve fibers directed medially and downward from the lower part of the ganglion superius, (4) a nerve filament coming from the vagus at the level of the hyoid bone and descending into the thorax. The rami from the lateral margin of the stellate and intermediary ganglia contain the sensitive cardio-aortic fibers which pass through these into the roots of the brachial and cervical plexuses, and from these to the spinal centers (fibers whose stimulation during an attack also produces the pain radiating into the left upper extremity). The second of the sections mentioned above seeks to interrupt those afferent fibers which, joined to the stellate ganglion, are directed upward toward the upper part of the neck and head. The third section, cutting the nerve bundle which probably represents the group of superior cardiac nerves, interrupts the afferent fibers which by way of the ganglion may reach alike the neck and head (along the cervical plexus and the carotid nerve). This section may cut a few of the less important vasomotor and cardio-accelerator nerves. The fourth section suppresses centripetal parasympathetic tracts related to the bulbar centers, which probably have also a vector function for cardio aortic sensibility. All these procedures were designed to intercept the sensory fibers which conduct the violent sensations of pain from the cardio aortic system to the centers of consciousness. It is possible that a certain number of fibers eluded section under this technique, but the great majority of these must have been cut, as the patient's satisfactory condition shows, 14 months after operation during which time there has been no attack.—*Riforma medica*, September 7, 1931

Studies in Sinus Infection—In a study of 101 cases of sinus disease, and 135 cultures taken therefrom, J Wynne Pugh sought to correlate the bacteria recovered with the reaction of the diseased sinus. Of the cultures 37 were pure and 98 mixed. From the tabulated figures he deduces the conclusion that the range of hydrogen ion concentration compatible with a full, happy, and useful life for all the bacteria recovered is identical with that of human cell life, and that no bacteria thrive especially, or are unusually discouraged, in any one pH. In correlating the type of sinus content and its reaction it was found that almost always the foul broken down, cloudy return from an acute or recrudescing sinusitis has an acid reaction relative to the normal healthy average pH of 7.5, the pH varying from 6.9 to 7.4. On the other hand, the healing sinus, which tends to have a firm clot of mucus, has a pH varying from 7.5 to 8.1, so that the use of the alkaline lotion in the irrigation of infected sinuses may have biochemical as well as mechanical reasons for its employment. Another and more startling discovery was that the bacterial flora of a diseased sinus changes continually. Several of

the cases investigated had cultures and pH estimations at intervals of one to two weeks, and it was decidedly the exception to find the same bacteria present at different examinations. The importance of this finding is seen when one considers the preparation of autogenous vaccines. It suggests that in the preparation of autogenous vaccines repeated cultures be taken first, and then only those vaccines be used which prove their specificity by the degree of reaction they cause on injection in trial doses. In seeking for the predisposing cause of sinus disease, Pugh observes that they have very much less sinus trouble in England than we do here. He is inclined to think that central heating is the cause of a good deal of sinusitis, though so far there is no proof. It might be possible to humidify some public schools and to use non-humidified pupils as controls, and rabbits might be subjected to similar investigations.—*The Laryngoscope*, October, 1931, xli, 10.

The Beginning of Chronic Renal Disease.—All renal disease, acute or chronic, is preceded by a disturbance in the regulatory apparatus of the vascular system, says R. Siebeck, in the *Deutsche medizinische Wochenschrift* of October 16, 1931. This vascular disturbance is wholly independent of the kidney condition, and furnishes a constitutional foundation for functional derangements and organic disease. The morbid picture which develops under these conditions frequently resembles that of so-called essential hypertonia, with general palpitation, loss of strength, tendency to air hunger, vertigo, and headache. In acute nephritis many of the symptoms arise not from the kidney disease but from this independent disturbance in the vessels. The heart, burdened by the increased blood pressure, may be reduced to a condition of permanent weakness, the more so if the resistance of the myocardium has been lowered by the attack of renal infection; the changes in the retina can be attributed likewise to vascular disturbances; the edema is apparently due to alterations in the metabolic exchanges between blood and tissues, not dependent on the kidneys but related to disturbances of the function of the endothelium. If the symptoms in severe acute nephritis are thus due in large part to the state of the vascular system, this system must play a decisive role in the development of chronic nephritis. Although the causes of chronic nephritis are not perfectly understood, Siebeck takes his stand with Volhard in regarding the vessels and the blood circulation of the tubules as of primary importance. It is reasonable to assume that the persistent abnormal engorgement of the vessels has brought about organic changes in them and in the tissues,—changes that are irreversible and which further induce a greater tendency to disturbances of circulation, thus creating a vicious circle. Frequently the acute stage of nephritis passes unrecognized, and the physician is not

called in until chronic changes have resulted from the insidious course of the disease. For a long time these cases must be judged chiefly on the basis of the blood pressure as the most important consideration. The hope of improvement in all these cases lies in reaching a diagnosis early enough to make it possible to institute a sparing treatment, calculated to save the kidneys and heart from overexertion. In any case, the leading symptom to be attacked in chronic kidney cases is nearly always the increased blood pressure.

Premature Contractions of the Heart in Children.—F. Antell reports three cases of premature systole of the heart in children. He states that the condition is relatively infrequent in children. In a series of 400 consecutive cases studied in the out-patient pediatric services of Beth Israel and Gouverneur hospitals no case of extrasystole was discovered. The largest number of cases are encountered during or shortly after acute infectious diseases. In the absence of other cardiac signs, the condition is usually benign and of little significance. Occasionally, however, premature contractions may be precursors of definite myocardial disease, as in one of the cases here described. This child developed a state of decompensation, a dilated heart and most irregular rhythm, resembling auricular fibrillation. What causes these premature contractions in apparently healthy hearts is still unknown. In recent years considerable evidence has been brought forward to prove that they may be explained on the basis of local circulatory deficiency resulting in increased irritability. Antell believes that hereditary influences play a part in idiopathic cases. In his first case there was a questionable family history of similar trouble in an uncle of the patient. In appraising the clinical and pathological significance of these premature contractions, there is an array of conflicting opinion. Antell is of the opinion that cases of idiopathic origin are of no importance clinically, require no treatment, should get no restriction of exercise, and can be practically disregarded. Cases of toxic or nervous origin call for treatment of the causative agent. Cases that follow in the wake of infectious disease require caution. In these the position of the cardiac borders should be the guide. A slight enlargement spells definitely caution for several weeks.—*Archives of Pediatrics*, October, 1931, xlviii, 10.

A New Treatment of Carbon Monoxide Poisoning.—Pometta, writing in the *Schweizerische medizinische Wochenschrift* of October 24, 1931, calls attention to the excellent results obtained by Artault de Vevey and others with the use of sodium hyposulphite in cases of acute carbon monoxide intoxication. According to the severity of the symptoms a solution of 8 to 20 gm. of the hyposulphite in a liter of water is

administered in the course of 24 hours. Thus each individual dose is 100 c.c., amounting to $\frac{1}{3}$ to 2 gm. of the substance, administered at intervals until the symptoms disappear, which in milder cases will be in 6 to 10 hours, and at most within 24 hours. To patients in a state of coma the remedy can be administered by means of a stomach tube or by enema, or if necessary it can be injected intravenously, giving 20 c.c. of a 10 per cent solution at each injection. The results are truly astonishing, the consciousness returning promptly. In some cases a state of depression and of muscular weakness remains for 2 or 3 days, but the headache disappears absolutely. Other untoward sequelae disappear little by little upon administration of coffee and the like. For a week the patient should still continue to take the sodium hyposulphite in dosage of 2 or 3 gm. per day. The intravenous use of this substance is useful also in other types of cases in which the tissues suffer from lack of oxygen which is at the bottom of carbon monoxide poisoning. It appears however, that the action of sodium hyposulphite is not of a chemical nature, as was formerly believed but that it has the effect rather of overcoming the state of shock of the organisms. Its action would thus be biologic rather than chemical. This method of treating carbon monoxide poisoning has quickly become widespread, and favorable results are reported from many directions.

Infarcts of the Myocardium—Attention is called by L. Gallavardin and Roger Fromont to cases of myocardial infarct of which the essential if not the only sign is paroxysmal ventricular tachycardia. It appears that no author has yet pointed out the absolute difference between such tachycardia in cases of grave heart disease and what may be called autonomous ventricular tachycardia. There is a close relation between coronary trouble (infarct of the myocardium) and ventricular tachycardia occurring in non asystolic subjects, who are in a state of general good health. By outlining 6 typical cases the authors show that these ventricular paroxysms have all the characteristics of paroxysms of Bouveret's disease, the sudden appearance in a patient who is in sinus rhythm and who presents no sign of cardiac insufficiency, the long duration of the attack, the monomorphism of the electric ventricular complex, which in fact betrays the existence of a center of abnormal excitation. Cases of this kind quite frequently follow crises of frank or concealed angina, but may also appear as isolated phenomena, in the latter case we are dealing certainly with myocardial infarct causing this form of paroxysmal ventricular tachycardia. In the absence of an earlier history of an attack of complete arrhythmia, the only certain sign by which the nature of the condition can be recognized is the dissociation which exists during the attack between the count of the heart beats at the heart

itself and that at the jugular notch, if the jugular beats (representing the auricles) are less in number, or about half, those of the ventricles, we can affirm that the patient has an attack of ventricular paroxysmal tachycardia. Apart from this finding, the diagnosis can be made only by the electrocardiograph, whose tracing will show independent auricular waves with a rhythmic value less than that of the ventricular waves. In more rare cases, these ventricular tachycardias symptomatic of infarct may appear in patients who are already asystolic, or they may give place to extrasystoles and to brief attacks simultaneously with attacks of long duration. Such facts establish the close relation that exists between infarctoid tachycardia and extrasystolic explosions of the common grave cardiopathies. In the present state of our knowledge, quinidine seems to be the only remedy capable of arresting one of these ventricular paroxysms of long duration—*Archives des maladies du coeur, des vaisseaux et du sang*, October, 1931.

Copper Treatment of Anemia in Infants Prematurely Born—E. Schiff and N. Joffe state that their own experiments have fully confirmed the good results recently reported by Lewis in America in the treatment of young children between the ages of 6 months and 7 years suffering from anemia. Although Smith administered both copper and iron, these authors found no advantage in this combination over the use of copper alone. The observation that small amounts of copper are effective in the prophylaxis and treatment of milk anemia argues that the development of this disease is not due to a lack of building materials which are necessary for the formation of hemoglobin (which in human beings contains no copper), but that the favorable effect of small amounts of copper is due to a catalytic action of this substance, which may be supposed to have an influence upon hemoglobin synthesis. So striking was the good effect of copper that the authors were induced to try its effect upon anemia in infants prematurely born, which has hitherto proved refractory to treatment. The mode of development of this type of anemia has never been explained, and the various hypotheses that have been presented have been for the most part untenable. The authors accordingly administered 10-20 drops of a 1 per cent copper solution once or twice a week to 12 prematurely born children, over a period of several months. The protocols of 3 of the cases in children 3, 3½, and 4 weeks old are given. In no case was any salutary effect observed with reference either to prophylaxis or to cure of the anemia. Hence it may be assumed that unlike alimentary anemia which is influenced favorably by administration of copper, the anemia of prematurely born infants remains wholly unaffected by such a treatment—*Klinische Wochenschrift*, October 17, 1931.

LEGAL

INSANITY — LIABILITY OF PHYSICIANS MAKING EXAMINATION

By LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

Physicians who make mental examinations for the purpose of determining sanity or insanity of an individual are sometimes thereafter confronted with a claim based upon alleged negligence in the making of such examination. That there is nothing new about claims of this character is clearly illustrated by a case that came before one of our Appellate Courts over twenty years ago.

In the case in question the husband of a woman came to a physician and said that he feared he would have to send his wife to a sanitarium; that for three or four years she had been acting strangely and for two or three years they had had a great deal of trouble. He further said there was nothing he could do to please her, that she had attacked him, had threatened him, and also threatened to injure herself. He told the physician that city life not agreeing with his wife, he purchased a home for her in the country. Instead of improving her health, this move proved detrimental to his wife's condition, for she insisted upon operating a wheelbarrow filled with heavy stones and that his advice that she desist in this was entirely disregarded. He further told the physician that for some years his wife refused to speak to him, but that she left notes in the house in the form of agreements which, although utterly ridiculous, he signed in order to keep peace in the family. The further history obtained by the physician disclosed that the man's wife had been a constant source of trouble and annoyance to the neighbors since on many occasions she screamed and screamed although there was no reason for her to do so. Substantially the same story the husband repeated to another physician. Neither physician was acquainted with either the husband or the wife. A short time thereafter, the husband requested the two physicians in question to make an examination of his wife to the end that if they found that she was insane and a proper subject for custody and treatment in some institution for the insane that she might be committed, after compliance with the legal requirements pertinent to the situation. The two physicians, pursuant to the husband's request made a joint examination of the wife, and after such examination certified that she

was insane and a proper subject for custodial care in an institution for the insane. Upon the husband's petition and the physicians' certificate the woman was committed to an institution.

Some time thereafter she brought an action against the two physicians in which she charged that the defendants made a false, pretended and grossly negligent examination of her as to her mental condition; that she was not insane at the time of the examination, or at any time, and that the defendants wilfully failed and neglected to use or exercise reasonable and ordinary care to ascertain her true mental condition. She further charged that the defendants failed to make a prudent and careful inquiry and to obtain proof as to whether she was sane or insane, and failed to exercise their best judgment as to her sanity, and further that with gross and culpable negligence they based their opinions upon false and interested statements made to them by the plaintiff's husband. The action came to trial and the jury awarded the plaintiff a verdict in the sum of \$25,000.

From the judgment entered upon this verdict, the defendants appealed to the Appellate Division. On the trial the plaintiff, after testifying that the defendants were introduced to her as nerve specialists, gave her version of the examination conducted by the physicians substantially as follows:

She said that the examination took less than fifteen minutes. That one of the doctors did not ask her any questions and the other physician asked her only a few. She further testified that the physicians took no notes and that she was asked by one of them on two or three occasions whether she ever thought of ending her life. She also testified that she was asked a few questions with respect to her experiences with her husband.

The defendants testified with respect to their joint examination substantially as follows:

The plaintiff was lying on a sort of lounge chair or steamer chair, covered with blankets. She seemed anxious. She was very pale in appearance when they went in, and then her face flushed, her whole manner changed and she showed intense anger and excitement. After the husband left the room the defendants

gave their names and said that her husband had asked them to make an examination, which they would be glad to do if she were willing, but that they did not wish to distress her, whereupon she said it was one of her husband's schemes to annoy her and he would ultimately drive her insane. When asked about her health, she said it was not very good, that there was sufficient cause—her husband—who forced her to work out of doors, and that she had to haul stones. She then rose and showed the path she had made outside. She said her husband had deliberately walked across the lawn to annoy her. Dr X asked her again about injuring herself, and she said she would not, that she would not bring disgrace on her family. The husband returned and she acted very angry towards him. She said she had to move her bed because of a leak in the roof. She became very much excited at four separate times during the examination. She would pale and flush and her pupils would dilate and her muscles would contract and she would sit up. In regard to her physical condition, she looked fairly well excepting that she was pale and very anxious, and she looked to be all right excepting during the period of excitement, when she would become excited and speak in a very loud voice. She became excited to the extent that she spoke and shouted in a very loud voice, and she showed great excitement during this time, and then again she would become more composed. As regards her physical condition, it was very fair. They did not make a record of her pulse, but Dr X took her pulse and it was somewhat accelerated. She appeared anæmic when Dr X looked at her first, but in looking at her again he found her color was very good, that her pupillary reflexes were all right, and the various reflexes were all right. Dr Y testified that after he and Dr X came to the plaintiff her husband said "I have brought these two physicians to examine you, because I thought you were sick, they will talk with you and will see if anything can be done for your good." Mrs A seemed out of patience. She appeared angry and made a remark to Mr A but made no other objection to their remaining there. Mr A stepped downstairs and left them alone with his wife. Dr Y permitted Dr X to do most of the questioning, nevertheless following what was said very closely. Mrs A was asked how she felt ill, and was asked to discuss the matter in general. She said that she had been feeling bad, had been nervous for some time, that she had a great many troubles at home, and that she was very much worried, that Mr A had been making trouble for her for a number of years, and that he was gradually getting worse, that, in her opinion, he was

anxious to obtain control of her property and was taking steps to drive her to commit some act which would permit of his obtaining the property, that it was part of the scheme for him to control her property, that these troubles had come on her within the past few years, that he had been annoying her in all sorts of ways, for instance, that on one occasion he entered her room, after having been working out of doors, removed a shirt in which he had been working and threw it on a chair on which one of her dresses was placed, she thought he did this with some malign intention to exasperate her, this had occurred a year or two before if the witness remembered rightly, and yet she brought that up as one of his supreme insults, as she called them.

The plaintiff, on the trial, called a number of lay witnesses, most of them her acquaintances and friends, who testified that in their opinion, specific words and acts of the plaintiff before and about the time of the examination were rational. The plaintiff did not offer any proof in support of the allegation in the complaint that the statements made by the husband to the physicians were false and pretended. Neither did she offer any proof that the defendants lacked the learning and skill ordinarily possessed by the average examiners in lunacy. The plaintiff did not offer any scientific or expert evidence showing or tending to show that the defendants had failed to follow proper practice in the making of their examination. In commenting upon this point, the court said:

"A striking feature in the plaintiff's case is the omission of any scientific or expert evidence as to the course pursued by the defendants in the examination, as to what was done that the average examiner in lunacy would not have done, or as to what was not done which such an examiner would have done under the circumstances of the case. We know insanity is a mysterious disease, that it may exist without physical indications, is often cunningly concealed so as almost or altogether to baffle detection even by a specialist, or may be so occult as to cause most eminent alienists to clash as to its existence in an instance. The diagnosis of it is recognized as a difficult task (Balfour Browne, *Medical Jurisprudence of Insanity*, 320, Mann's *Medical Jurisprudence*, 113) Wharton & Stille on *Medical Jurisprudence* (Vol 1, Sec 1240) write 'In brief, the task of a physician when he examines a patient for certification is to make a diagnosis. If, for any reason, he is not able to make a diagnosis, he should not sign the certificate. The whole art of diagnosis may be involved in the case, and there is no rule for it except to have a reliable knowledge of insanity.' It seems to

me that the very nature of the subject—the question of negligence in a diagnosis—would almost preclude a jury from passing upon it by their common knowledge unaided by any scientific or expert information whatever, or by the testimony of any witnesses of special knowledge and skill. Yet there is not in evidence any standard for comparison of the conduct of the defendants with that which was required of them.”

The court concluding that the plaintiff had failed to prove any negligence in the making of the examination on the part of the defen-

dants or either of them, reversed the judgment and ordered a new trial.

It is of the utmost importance for the protection of the examiners that they should make a very careful examination of the patient so that if any claim thereafter arises they will be in a position to fortify and sustain their findings.

An examiner in lunacy who is not given an opportunity to make the thorough examination which he deems necessary should refuse to sign a certificate in connection with such examination.

BURN FROM DIATHERMY TREATMENT

In this case a physician, specializing in x-ray work and diathermy, was consulted by a woman about forty years of age who complained of a pain in the back and right arm. The doctor examined her and found that she was suffering from distortion of the joints of both hands and clubbing of her fingers. He diagnosed her condition as arthritis and recommended diathermy treatment. He administered to her a treatment with his machine, which was a standard make, attaching one plate from the machine to her arm and the other to her hand, using sheets of tinfoil on heavy zinc which was wet and soaped, bandaging the plates to her arm and hand. He then applied the current and gave her a 500 m.a. dosage of about twenty minutes duration. The patient made no complaint of the heat and appeared to suffer no ill effects from the treatment, the doctor watching her meanwhile. She left the doctor's office without any complaints, but about two hours later she returned, exhibiting to him a few small blisters on her wrist close to the spot where the zinc plate had been bound to her hand. The doctor dressed the blisters which seemed to be trivial in extent and sent her home.

Apparently the burn occurred by reason of the woman moving her hand during the treatment, causing the electrode to become dislodged and permitting a spark to jump through to the wrist.

Subsequent investigation of the matter disclosed that the patient had been suffering from syringomyelia, a rare disease of the nervous system, which had de-sensitized the skin that had been burned so that she was unable to tell during the application of the treatment whether the heat was excessive.

The patient subsequently consulted a surgeon with respect to said burn. Upon examination of her wrist he found considerable swelling and ulceration, with a condition of septic arthritis. At his advice the patient submitted to an operation to remove so much of the burn from her wrist as had become necrotic. Under a general anæsthesia he opened up the affected area and found a bad condition of necrosis and removed a large amount of bone from her wrist and sawed off the end of the radius. The condition thereafter improved normally, but the end result was that the patient lost all motion in her wrist. She was able to move her fingers but unable to grip anything with her hand. Likewise, the motion of her elbow had become somewhat restricted.

A law suit was instituted against the doctor who had administered the diathermy treatment, claiming that through his negligence she had sustained a serious burn on her arm due to which she had completely lost the usefulness of the said arm. Damages were demanded in the total amount of \$60,000.

The case came on for trial before a judge and jury and the plaintiff proved the administration of the treatment by the defendant and her injuries, but introduced no proof showing that the doctor was in any way negligent. At the end of all the testimony the court directed judgment for the defendant.

An appeal was taken to the Appellate Division on behalf of the plaintiff, but was never actually brought on for argument. After a year had elapsed a motion was made to dismiss the appeal for want of prosecution which was granted, finally terminating the matter in favor of the doctor.

NEWS NOTES

TEACHING THE PUBLIC THE NEED FOR PROPER MATERNITY CARE

In 1918 the Maternity Center Association was organized through the effort of a group of obstetricians who, after making a study of conditions in New York, interested some public-spirited citizens in a plan for improved maternity care among certain groups of people to whom such facilities were lacking.

In 1919 the Association became incorporated and for five years conducted demonstration prenatal work, endeavoring to reach prospective mothers early in pregnancy and then get them under medical supervision.

In 1922 emphasis on prenatal care alone was discontinued. The Association concentrated on a program of complete maternity care in one small district and expanded the scope of its educational work.

A study of the records of 4,726 pregnant women cared for by the Association was made by Dr. Louis I. Dublin and published in the *American Journal of Obstetrics and Gynecology* (December, 1930). This report showed a maternal mortality rate of 24 for mothers cared for by the Association as compared with a rate of 62 for the mothers in the same district not under its care. The obvious difference in the care received by the two groups was that the Maternity Center Association group had early and constant medical supervision.

In 1930 the Maternity Center Association launched a year's campaign, which culminated on Mother's Day in 1931, during which efforts were made to reach as many persons in this country as possible through publicity methods which stressed the facts that the puerperal death rate in the United States was unnecessarily high, that it could be reduced greatly by adequate and skilled obstetric care, and finally to educate the public in the essentials of such care. Daily and weekly newspapers, magazines and trade journals all over the country carried the material which the Maternity Center Association sent out. The Metropolitan Life Insurance Company, the Borden Company, and Parke Davis and Company devoted newspaper and magazine display advertising to the importance of adequate maternity care. Governors and mayors issued proclamations and health commissioners wrote articles and broadcast over the radio, ministers preached sermons, news reels in every theatre in the United States showed Mrs. Theodore Roosevelt, Sr., speaking at the Association's luncheon in New York on May 19 of last

year in behalf of the work of the organization.

In its campaign for the current year the Maternity Center Association asks the support of the members of the Medical Society of the State of New York. It will endeavor to enlist the interest and help of every practising physician in the State by circulating among them in reprint form, for distribution among his or her patients, the statement which follows. It is hoped by this means to develop a better knowledge of the need for adequate maternity care which will result in a situation mutually helpful to patients and their physicians. During the month of January, press releases all over the State will call attention to this campaign and to the participation of the State Medical Society in this movement.

The medical activities of the Association are under the immediate and close supervision of a Medical Board, made up of the following members: Dr. George W. Kosmak, chairman, Drs. S. Josephine Baker, George L. Brodhead, Haven Emerson, Caroline S. Finley, James A. Harrar, Leon S. Loizeaux, Philip Van Ingen, George Gray Ward, Wilbur Ward, Benjamin P. Watson, Herbert Wilcox, and Hervey C. Williamson.

Dr. Kosmak submitted a draft of the proposed circular statement to the Committee on Public Health and Medical Education of the Medical Society of the State of New York on October 8, 1931. The Committee approved and authorized its distribution to the practicing physicians in New York State, to be given by them to their pregnant patients. Later in the day the action of the committee was approved by the Executive Committee of the Council.

The following is the text of the circular, copies of which may be obtained from the administration headquarters of the Maternity Center Association at 1 East 57th Street, New York, telephone, PLaza 3 2066.

A MESSAGE TO EXPECTANT MOTHERS AND FATHERS FROM THE NEW YORK STATE MEDICAL SOCIETY

Motherhood is natural and should be normal. If you do as your doctor advises, you should have no reason to worry about having your baby.

Every Pregnant Mother Needs a Doctor—the best one available—to care for her from

the time she believes she is pregnant until he says she is able to resume her regular activities and responsibilities and to care for her baby. Her doctor will make a complete examination. He will take her blood pressure and examine her urine, measure her in order to determine whether the passages are large enough for the baby to be born without difficulty. He will make an internal examination, too. He will want to see her every three or four weeks or oftener throughout pregnancy to examine her urine and take her blood pressure, so he may know all about her condition as the baby is developing and be able to give her the best of care when the baby is being born. He will help her to decide whether to go to a hospital or to stay at home for the baby's birth. He will want to see her and the baby several times after the labor. He will examine her two and three months later to make sure everything is all right before she undertakes the full care of her home and baby.

Prospective mothers should observe the following directions in addition to what the doctor may order: Eat simple balanced meals—meat once a day, two green vegetables, canned or cooked fruit and one quart of milk. Sleep eight hours every night with windows open. Rest one-half hour morning and afternoon. If you are not tired, take a daily walk. Bathe daily, preferably a shower. Do your work with the windows open. Wear clothes that are light and loose and hang from the shoulders.

Labor begins with a pain in the back, with or without discharge. As soon as labor begins, send for your doctor. Take things easy until he gets there.

Ask him *NOW* for his card or telephone number so you will be able to call him immediately.

ATTACH HIS PHONE NUMBER TO THIS CIRCULAR AND PLACE IT IN A PROMINENT PLACE.

BABY'S SUPPLIES

The following list of baby clothes and toilet necessities may be modified as to material, quantity and quality to suit the individual taste and pocket-book:

- 48 Diapers, 20 inches by 20 inches
- 3 Slips
- 3 Bands 6 by 7 inches
- 3 Shirts size 2, cotton and wool, or silk and wool
- 3 Night dresses
- 3 Dresses
- 3 Squares, 36 by 36 inches
- 6 Quilted Pads 11 by 16 inches
- 2 Rubber Pads, 11 by 16 inches
- 1 Hair pillow or felt pad, or folded blanket, for mattress.
- 1 Basket or box for bed 15 by 30 inches
- 1 Oilcloth or rubber pillow case for mattress.
- 2 Muslin pillow cases for mattress.
- 2 Crib blankets, small size
- 2 Towels, soft
- 2 Wash cloths, old pieces of linen or underwear
- 1 piece pure white soap
- 1 package absorbent cotton
- 1 package of toothpicks
- ½ pint albolene
- 1 Covered pail for soiled diapers
- 1 box of 20 Mule Team Borax
- Toilet Tray to be fitted with:
 - Jar of boiled water
 - Jar for large cotton swabs
 - Jar for small cotton swabs
 - Jar for cotton
 - Soap for pincushion
 - Bottle for boiled water
 - Jar for nipples
 - Flat dish for soap
 - Flat dish for oil
 - Safety pins
 - Nursing bottle
 - Paper cornucopia
 - Anticolic nipples
 - Bottle caps

MEDICAL ECONOMICS

TWO QUOTATIONS AND SOME COMMENTS

"There is a perfectly appalling ignorance in every quarter about economics, about the ways in which men work and live together

"Indeed, if there is one stark fact that stands out in the world's experience of the past two years, it is that the number of people on the planet who understand clearly *what* has been happening and *why* must be a pitiable handful—and that among them are probably not to be included most of our *soidisant* 'experts'. In other words, we now see that this great world-machine, human society—a machine that nobody made, that made itself—has been lumbering forward through time, creaking, groaning, emitting fearsome explosions every now and then, and suddenly it has become clear to most of us, apprehensive passengers, that there is not even a driver's seat on the immense contraption, that there is not a soul at the helm of it who understands competently how it works, that its distracted tenders (whom we have heretofore blindly trusted) know no more than we do, and often less, about its complex mechanism, but are simply running about, worried and quarrelling, fastening a bolt here or loosening a screw there—one not knowing nor caring what another does. In certain departments of knowledge, obviously, it is not of any immediate importance if the great body of living human beings happen to be in abysmal ignorance. It may be a sad fact, for instance, that only a dozen people in the world can understand Mr. Einstein's theories, but at least there is no very pressing reason (so far as we can see) why more should, at this time. This is true of many things. It is not true of economics. Here a general ignorance matters, matters vitally, affecting so intimately, as it does, the present and future of every single one of us

—Harry Sherman

"Since the Great War, the economic stresses of the world have become more and more painful and distressing. By comparison, preceding ages are beginning to assume an air of the most idyllic tranquility. Now we all begin to realize we are living in the breakup of whatever system existed before our time, and that in great disorder a new system may be coming into being. All sorts of forces are at work disorganizing us now, but with a tantalizing air of producing some larger strange organization to which we must adapt our lives. We work, and the things we make are taken away and we see no more of them. Our streets are full of strangers who pass and give way to other strangers. Great factories arise in our familiar landscape, and we do not under-

stand why they have arisen or what they produce. We buy and consume exotic foods. We are employed, we are thrown out of employment, things become dear, or cheap, or inaccessible and we cannot trace the causes of these fluctuations.

"It seems all beyond our control. We can not find out who controls it. Is anyone controlling it? The newspapers tell us this or that about it. They are disturbing and alarming. Vast multitudes, we learn, millions are being thrust out of employment. There is plenty, locked up. There are dire want and misery. Then we find ourselves called upon to decide between politicians who demand that this shall be done and politicians who demand that that shall be done. It appears that we in our muddled multitudinousness are being called upon to make decisions. This immense tangled affair, we gather, is our affair. In various rather obscure ways we have been made responsible for it. We have to vote.

"But how can we vote when we do not get the hang of it? Has anyone got the hang of it? Are there any people anywhere in our world today who have a really comprehensive vision of the economic world process as one whole? Apparently not. And yet we ordinary people have it thrust upon us, that whatever control can be exercised over this immense complex tumult of world change, must be exercised through our voting and our assent."

—H. G. Wells

With some such appreciation of the magnitude and chaos of the problem, the State Society Committee on Medical Economics has undertaken its job.

No magic solution of the ills of society nor even of the lesser field of medical economics has been contemplated. Our most ambitious hope is that we may lay a foundation, a plan, upon which we and our successors may build. At every turn of our thoughts we are confronted with the need of facts from which to analyze or upon which to predicate conclusions.

In the present organization of society many vexations and injustices fall to the lot of the doctor. We may seek relief from some of these by recommendation of change in the statute law. In others our only recourse will be found in a clear statement of principle, with the hope that as the organization of humanity progresses it may shape that growth. In every instance there is the outstanding need of compiled facts or data upon which to establish our point of view.

The late President Wilson gave high recognition to the principle of policy of "collective

bargaining." Thoughtful observers of current events have noted the baneful sequences of fanaticism fostered by a small but well-financed and well-organized minority. What a different thing we can make of a group consciousness, of a united and expressed will of a highly educated and broadly experienced class of men and women? A collective judgment balance by living contact with every level of human life, with every industry and human effort, with every vocation and avocation known to the mind of man.

We, a part of this great living mass, must now sense our group-being, our group-privileges, and our group-responsibilities. An in-

telligent class of citizenry, too long we have been only professionally minded. We must surely assume our more complete life-experience. We must open our minds and apply our influence to the affairs of the community and of the world.

Medical economics cannot be a mere quasi-philosophy of ways and means to greater profit from sick-care. No! It must be the establishment of principles and laws to relate medicine to the growth and maintenance of family and community life, wherein there is a fair and proper balance between work and awards, with justice to all—FREDERICK E. ELLIOTT,

For the Committee on Medical Economics.

COMMITTEE ON LEGISLATION

Dr. Harry Aranow, Chairman of the Committee on Legislation, has sent the following letter to the secretaries of the County Medical Societies:

Condition of Medical Practice: The Committee on Legislation has been entrusted with the task of ascertaining how the medical practice act is operating in the state. We think of no better way than to inquire of the secretaries of the County Societies.

Will you please let us know what the conditions in this regard are in your county? If the law is not being properly enforced or administered, let us have the particulars, using the enclosed envelope for your reply.

While we are writing you, we wish to suggest that there is great need for each County Society to develop some concrete plan for taking care of the sick unemployed this winter. By so doing we can anticipate the flood of relief bills we expect will be presented to the legislature. If a considerable number of County Societies adopt a relief program and inform us of their action, we shall be in a better position to prevent the enactment of a general uplift program in which the physician traditionally receives little consideration.

Will you please bring these matters to the attention of your County Society at its next meeting and inform us of the action taken?

Dr. Aranow has also sent the following letter to the Chairman of the Legislative Committees of the County Medical Societies:

Chiropractic: Let us remind you of the urgent necessity of immediately calling upon your Assemblymen and Senator with well prepared argumentative proof that chiropractic is a fraud and has no scientific basis whatever.

D. D. Palmer, its originator and promoter, claimed to be able to heal by laying on of hands, from which probably comes the name "Chiroprac-

tic." In developing his philosophy he helped himself liberally from osteopathy. His son, "B. J.," took over the school while his father was in prison and sold widely a correspondence course in chiropractic. The school at Davenport—and there is no other that was ever nearly so large—has gone into decline in the last few years.

Chiropractors do not believe in germs as the cause of disease, but do teach that the spinal vertebrae become displaced as to press on the spinal nerves and all disease is the direct result of such pressure. Anatomists contend that displacement that would cause such pressure is impossible, except as a result of trauma, and that the ligaments bind the vertebrae together so tightly that no man can move one upon another even a fraction of an inch. Chiropractic is pure quackery and humbuggery.

Impress upon your legislators, also, the great injustice that would be done to the public by permitting osteopaths, who have never learned to use the knife or believe there can be any virtue in drugs, to practice Surgery and prescribe drugs. Osteopaths, you know, take the same examinations under the Medical Examining Board as physicians, and because of this they claim they should not be denied any privileges accorded us, but they neglect to state that they are required to present fewer qualifications for entering the examinations; namely, no knowledge of operative surgery nor the two years of pharmacy and materia medica required of us.

The legislators will appreciate the danger of granting anybody a license to prescribe drugs who knows no more than the legislator himself.

Do not delay in securing the cooperation of the legislators' family physicians, and impress upon them that they must do more than simply tell the legislator to vote against such bills. He, too, must give reasons for his opposition.

THE NEW YORK ACADEMY OF MEDICINE

The annual meeting of the New York Academy of Medicine was held on the evening of Thursday, January 7, in its building at 2 East 103rd Street, New York City. The formal meeting was preceded by a testimonial dinner given to the Director of the Academy, Dr. Linsly R. Williams, which was served in the exhibition hall, and was attended by over two hundred Fellows.

The business before the annual meeting was the reception of the reports of the officers and committees. Since these dealt with a multitude of details of the broad field of the activities of the Academy, they were presented by

title only, but will be published later. The exception was the remarks of the Director who paraphrased his formal report by giving an informal review of the work of the Academy during the eight years of his directorship. He also gave a picture of the plans for the future including the ultimate development of the Academy into a Medical Museum with the scope of the Metropolitan Museum of Art, and the American Museum of Natural History, after plans which have been urged by Dr. D. Bryson Delevan (See page 84).

The reports will be published in an early issue of the Bulletin of the Academy.

OTSEGO COUNTY

The annual meeting of the Otsego County Medical Society was held at the Fox Memorial Hospital on Tuesday, December 8th. The following officers were elected for 1932:

President—Dr. Harrie V. Frink of Richfield Springs

Vice-President—Dr. James Greenough of Coopers town

Secretary-Treasurer—Dr. F. E. Bolt of Worcester

Censor—Dr. E. C. Winsor of Schenectady

Delegate to the State Convention—Dr. A. F. Carson of Oneonta

Alternate—Dr. L. C. Warren of Franklin

Dr. J. H. Powers and Dr. Charles A. McCoy of Coopers town were elected to membership.

At the scientific session Dr. Arthur W. Elting gave a clinical lecture of dressing and treatment of wounds resulting from automobile and gun shot accidents. The talk was most interesting and instructive. Dr. Elting brought out many new ideas of modern surgery that have been adopted since the war.

A very satisfactory duck dinner was served in the dining room at the hospital to the thirty-two members present.

This meeting had the largest number of members present in several years.

A. H. BROWNELL, *Secretary*

RENSSELAER COUNTY

The annual meeting of the Medical Society of the County of Rensselaer was held in the Troy Health Center at 8:40 p.m., December 8, 1931.

The officers of the society as presented by the nominating committee at the last meeting were regularly elected to their respective positions. They are as follows:

President—Dr. J. B. Burke

Vice-President—Dr. W. W. St. John

Secretary—Dr. C. J. Handron

Treasurer—Dr. O. F. Kinloch

Censors—Dr. J. H. Bissell and Dr. C. W. Hamm

Delegates to the House of Delegates—Dr. A. J.

Hambrook and Dr. J. H. Reid

Alternates—Dr. J. J. Quinlan and Dr. F. W. F. Caird

President-elect, Dr. J. B. Burke, gave a two-minute speech asking for the cooperation of the membership, and for suggestions relative to monthly programs during the coming year.

The censors reported favorably on Dr. Charles R. Lewis, Dr. Wm. B. McDonald, and Dr. Frank Davenport, and they were elected to the regular membership. Dr. F. J. Scott was elected to the Associate membership.

Dr. W. W. St. John, representing the Economics Committee, gave a detailed report on "The Relation Between the Physician and Insurance Carrier."

The meeting then adjourned to reconvene in the ballroom of the Hendrick Hudson Hotel at 7:00 p.m., December 9, 1931, at which event nearly the entire membership attended. At the close of a turkey dinner, Dr. John B. Harvie of Troy, N. Y., gave a very interesting talk entitled "After Fifty Years."

Dr. Gabriel Tucker of Philadelphia, Pa., gave an excellent address on "Bronchoscopy," with a lantern slide demonstration.

WM. B. D. VAN AUKEN, *Reporter*

DUTCHESS-PUTNAM COUNTIES

A regular meeting of the Dutchess-Putnam Medical Society was held Wednesday evening, December 9, 1931, at St. Francis Hospital, Poughkeepsie, N. Y., and was called to order by the Vice-President, Dr. W. A. Krieger, at 9:00 p.m.

The minutes of the previous meeting were read and approved.

The following was a report of the nominating committee:

President—Dr. William A. Krieger

Vice-President—Dr. Samuel E. Appel

Secretary-Treasurer—Dr. Howard P. Carpenter

Associate Secretary—Dr. E. Gordon MacKenzie

Delegate (1932-33-34)—Dr. William A. Krieger

Alternate Delegate (1932-33-34)—Dr. J. N. Boyce

Censors—Drs. A. L. Peckham, A. W. Thomson, Scott Lord Smith

Councilor—Judge G. V. L. Spratt

Dr. Charles Lerner, Instructor in Dermatology, N. Y. Post-Graduate Medical School of Columbia University, gave a paper on "The Etiology and Treatment of Nevi," illustrated with lantern slides.

The meeting adjourned at 11:00 p.m. for refreshments.

Present: Drs. Toomey, Rosenthal, J. N. Boyce, Maloney, Boyce, R. Deyo, J. H. Dingman, Card, Sadlier, Roberts, Brown, Stoller, Appel, Voorhees, Borst, MacKenzie, Krieger, Simon, Davison, Thomson, Sobel, Cavanaugh, C. E. Lane, H. P. Carpenter, Lerner, Poucher, Stibbs, Gosse, Leonidoff, Harrington, Benson, Smith, Harold Crispell, G. E. Lane. 33.

H. P. CARPENTER, M.D., *Secretary*.

TIOGA COUNTY

The Annual Meeting of the Medical Society of the County of Tioga was held at the Green Lantern Inn with a dinner at seven-thirty P. M., Tuesday, December 1, 1931. Thirty members and guests were present making the largest attendance on record for the Society.

The following officers were elected for the year 1932:

President—Dr. W. A. Moulton, Candor, N. Y.

Vice President—Dr. F. C. Carpenter, Waverly, N. Y.

Secretary-Treasurer—Dr. I. N. Peterson, Owego, N. Y.

Censors—Drs. A. C. Hartnagle, Berkshire, N. Y.; E. E. Bauer, Owego, N. Y., and E. S. Beck, Owego, N. Y.

Delegate to State Society—Dr. G. S. Carpenter, Waverly, N. Y.

The President Elect appointed the following committees:

Public Health—Drs. A. C. Hartnagle, Berkshire, N. Y.; H. L. Knapp, Sr., Newark Valley, N. Y.; E. E. Bauer, Owego, N. Y.

Public Relations—Drs. G. S. Carpenter, Waverly, N. Y.; A. M. Fisher, Spencer, N. Y.; C. J. V. Redding, Owego, N. Y.

Legislative—Drs. G. M. Cady, F. A. Carpenter and F. H. Spencer.

Medical Economics—Drs. L. S. Betowski, Waverly, N. Y.; H. L. Knapp, Jr., Newark Valley, N. Y., and W. D. Brown, Nichols, N. Y.

Program—Drs. L. D. Hyde, Owego, N. Y., and E. S. Beck, Owego, for March meeting; Drs. W. L. Seil, Waverly, N. Y., and W. H. Doolittle, Lockwood, N. Y., for June meeting; Drs. L. S. Betowski, Waverly, N. Y., and G. S. Carpenter, Waverly, N. Y., for September meeting; Drs. G. M. Cady, Nichols, N. Y., and A. C. Hartnagle, Berkshire, N. Y., for December meeting.

The report of the Treasurer showed a balance on hand of \$6.70.

Dr. W. L. Seil, Waverly, N. Y., was elected to membership in the Society.

Dr. C. S. Johnson, Spencer, N. Y., had his name transferred from membership in the Livingston County Society to membership into this Society.

The scientific program consisted of the exhibition of sex reels of medical movies by Dr. D. W. Stark of Buffalo.

EUGENE BAUER, *Acting Secretary*.

OSWEGO COUNTY

Dr. J. J. Brennan, Secretary of the Medical Society of the County of Oswego, asks that a correction be made in the third paragraph of the report of the meeting of the Society printed on page 36 of the January first Journal so that the paragraph will read:

"On motion it was decided that the Medical

Society of the County of Oswego will not adopt the fee schedule formulated by the Committee on Medical Economics of the Medical Society of the State of New York and the Insurance Company carriers; but our County Society will be guided by a fee schedule formulated by our own Committee on Economics.

ORANGE COUNTY

The following account of the meeting of the Orange County Medical Society, at which forty doctors were present, appeared in the Middletown *Times-Herald* of December 2, 1931

"Dr Samuel W Mills of Middletown was elected president of the Medical Society of Orange County at the hundred twenty-fifth annual meeting of the organization last night at Mitchell Inn Dr Mills succeeds Dr E C Waterbury of Newburgh, retiring president He was vice-president in 1931

"Dr Hilton J Shelley, city health officer here, was elected for the twenty-fifth consecutive year as secretary and treasurer of the organization Dr M R Bradner of Warwick was chosen vice-president

"The Board of Censors for the 1932 term includes Dr W W Davis of Chester, Dr Harry Pohlman of Middletown Dr Edgar Cuddeback of Port Jervis and Dr W H Snyder of Newburgh

"Dr M A Stivers and Dr J B Hulett were

chosen delegates to the State society, with Dr L C Waterbury of Newburgh and Dr J D Mars of Florida as alternates Dr Robert Cordner school health officer here, was elected first district branch delegate

"During the business session, which followed dinner at seven o'clock, four new members were elected They are Drs E H Douglas and Leo C DuBois of Newburgh and Raphael Spano and Lawrence Lief of Middletown The Committee of the County Unit was to continue to function under chairmanship of Dr J B Hulett, it was decided Drs W W Davis, H J Shelley, Frank Bullard and Myron Osterhout comprise the health committee, and were to meet today at two o'clock with the Board of Supervisors to discuss ways and means of obtaining financial backing for their work

"Dr Charles McKendree, consulting neurologist of Roosevelt Hospital, New York, was a guest at the meeting He led a brief discussion of brain lesions"—H J SHELLEY, *Secretary*

CHAUTAUQUA COUNTY

The annual meeting of the Chautauqua County Medical Society was held on Wednesday, December sixteenth, at the Hotel Jamestown, Jamestown, N Y Dinner was served at 12 30 P M, followed by a business meeting and scientific session, with about fifty members in attendance The following officers were unanimously elected

President—Dr Joseph Rieger, Dunkirk

1st Vice President—Dr E L Hazeltine, Jamestown

2nd Vice President—Dr W J Sullivan, Dunkirk

Secretary—Dr Edgar Bieber, Dunkirk

Treasurer—Dr F J Pfisterer, Dunkirk

Censors—Drs L W Powers Westfield, J H Kellogg, Bemus Point, and L D Bowman, Jamestown

Delegates to State Society—Drs D W Buckmaster, Jamestown, and Dr Edgar Bieber, Dunkirk

Drs J N VanderVeer and Albert Pfeiffer of Albany presented a most interesting and instructive symposium on syphilis its symptoms and treatment, from the viewpoint of the State Society and the State Health Department

EDGAR BIEBER, *Secretary*

ULSTER COUNTY

The annual meeting of the Medical Society of the County of Ulster, held on December 8, 1931, was outstanding in that it proved that the physicians of the county were interested in the administration of the Public Welfare Law The Society appointed a committee to meet the Kingston City Board of Charities and the Ulster County Board of Supervisors and arrange to have the attending physician paid whether caring for indigents in their homes or in hospital wards

The Medical Society of the County of Ulster pledged the amount of four hundred and sixty two dollars to furnish the lobby of the new Ulster County Tuberculosis Hospital, and it was duly collected at once

The question of caring for the sick unemployed in the present emergency was discussed, and the society finally voted that the County Society cooperate with the local Emergency Welfare Board and render any services they may look for

Dr Thomas F Crowley of Kingston, N Y, was appointed Reporter for the County Society for the year 1932

The election of officers was followed by the retiring President's address The attendance was fifty-eight per cent of our membership, some men driving over thirty miles to attend

R H VOSS, *Secretary*

ALBANY COUNTY

The annual meeting of the Medical Society of the County of Albany was held in the auditorium of the Albany College of Pharmacy on December 14, 1931, with the president, Dr. Charles K. Winnie, Jr. presiding.

The secretary reported a membership of 250 with an average attendance of 91 at the meetings.

It was pointed out that during the year 26 subjects relating to scientific and economic medicine were presented by 28 speakers; and of these 18 were members of our society and 10 visiting speakers. It is worthy of note that one entire meeting was devoted to a consideration of the much discussed workmen's compensation problem, and an opportunity was provided for an enlightened membership on certain phases of this subject.

The high water mark of the year was the celebration of the 125th anniversary of the founding of the society. This took the form of a dinner at the De Witt Clinton Hotel, on October 28, 1931. Over 150 physicians gathered to commemorate this event. The principal address was made by Dr. George W. Crile of Cleveland, and he was followed by Dr. William D. Johnson, President of the Medical Society of the State of New York, and the Honorable John Boyd Thatcher, 2nd, Mayor of Albany. Our President, Dr. Charles K. Winnie, gave an address which was a notable resumé of contemporary local and medical history during the first century and a quarter of our existence.

The Committee on Public Health reported that the State Department of Health had made a public health survey of the City of Albany.

Dr. Arthur J. Bedell, Chairman of our Board of Censors, reported that twenty-two physicians had registered in the County Clerk's office during the year. It was also reported, with pleasure, that no member had been brought before the board of censors.

Dr. Francis W. Dodge, Secretary of the Committee on Medical Economics, stated that as a result of a conference with members of the society, it suggested that the president appoint a committee of physicians to meet with a similar committee selected by a group of insurance carriers for the purpose of modifying the compensation practice so that there would exist:

1. A competent free choice of physician by the patient.

2. The formation of an appeal board by the parties concerned (physicians and carriers) to which questions of mutual interest or differences may be referred for discussion or adjudication.

No steps in this direction have as yet been taken.

The following officers were elected for 1932:

President—Dr. Arthur M. Dickinson

Vice-President—Dr. Richard A. Lawrence

Secretary—Dr. Homer L. Nelms

Treasurer—Dr. Frances E. Vosburgh.

HOMER L. NELMS, *Secretary*.

BRONX COUNTY

A regular meeting of the Bronx County Medical Society, held at Elsmere Hall, on December 16, 1931, was called to order at 9 p.m., with the President, Dr. Smiley, in the Chair.

The following physicians were elected to membership: Drs. Jacob H. Ackerman, Abraham L. Ceasar, Jacob Clahr, John V. D'Angelo, David Louis Engelsher, Philip Factor, Charles Kent Gould, Isidore Koulack, David Mesnik, Edward A. Pfeiffer, Pasquale A. Piacentine, Morris A. Raif, Henry Reiter, George Schwartz, Samuel Sherman, Solomon B. Singer, Anthony P. Vernaglia, Max J. Weinstein, Hyman Willinger, and Philip B. Wahrsinger (Associate Member).

Dr. Lefcourt, Chairman of the Social Committee, reported on the beefsteak dinner and show held on December first. The profit is to be devoted to the relief fund.

Dr. L. A. Friedman submitted a report for the Committee on Public Health. He referred to the recommendation of the committee that the

society again favor the passing of a regulation by the Board of Education to the effect that children on admission to school present a certificate of immunization against diphtheria.

Dr. Bick, Chairman of the Special Committee on Physiotherapy, reported on a recent meeting of the State Physical Therapy Committee, at which a plan was drawn up whereby a course will be given on physiotherapy, which will be open to all members of the county societies. This course will be given at six hospitals in New York City.

The scientific program proceeded as follows:

1. The Role of the Adrenals in Health and Disease, Max A. Goldzieher.
2. Disease of the Pituitary with Special Reference to Tumors, Leo M. Davidoff.

The papers were discussed by Drs. Emanuel D. Friedman and Cornelius G. Dyke.

I. J. LANDSMAN, M.D., *Secretary*.

ROCKLAND COUNTY

The Annual Banquet of the Medical Society of the County of Rockland was held at the Hotel St George, Nyack, on the afternoon of Wednesday, December 2nd, 1931. Thirty-eight members of the Society were present.

The following officers were elected for the year 1932: President, Dr S R Monteth of Nyack, Vice-President, Dr George M Richards of Stony Point, Secretary (re-elected), Dr William J Ryan of Pomona, Treasurer (re-elected), Dr Dean Miltmore of Nyack, Chairman of the Board of Censors (re-elected), Dr R R Felter of Pearl River, Chairman of the Legislative Committee (re-elected), Dr C D Kline of Nyack, Chairman of the Committee on Public Health and Public Relations (re-elected), Dr Royal F Sengstacken of Suffern, Chairman of the Membership Committee (re-elected), Dr G F Blauvelt of Nyack, Delegate to the State Society (re-elected), Dr George A Leitner of Piermont, Alternate Delegate (re-elected), Dr C D Kline of Nyack.

The Society voted to contribute \$200.00 from the funds of its treasury to the Unemployed Relief Bureau of Rockland County, and \$50.00 to the Reconstruction Hospital at West Haverstraw for the children's Christmas Fund.

Different phases of Public Health was the topic of discussion for the day, and the speakers were as follows:

"Public Health and the Physician," William J Ryan, M.D., of Pomona.

"Public Health and the Layman," A J Miller, Esq., of Ramapo.

"Public Health and the State," Richard Slee, M.D., Deputy Commissioner of Health, Westchester County.

Dr Ryan stressed the close relation that exists between curative and preventive medicine. He stated that the public health work cannot be confined to the few local health officers and boards

of health, but that the practicing physician who is daily coming into intimate contact with families is in the position to teach preventive medicine. The State Medical Society in the last few years is appreciating more and more its responsibility in this field of work and is urging the organization of committees in the county medical societies for the purpose of surveying the local health situation and to adopt progressive programs.

Mr A J Miller, an official of the Rockland County Branch of the State Charities Aid Association, and a member of the Child Welfare Board, and who was a guest of the Society, discussed the activities of the Social Welfare Organizations in Rockland County. The work of the State Charities Aid Association in the placement of dependent children and the Mother's Allowance was especially emphasized. Mr Miller made an appeal to the medical profession to cooperate in the unemployed relief situation which is now existing in the county.

Dr Richard Slee, Deputy Health Commissioner of Westchester County, where a county health unit is now in operation, explained the great value of the centralized organization. Dr Slee, who had been a District State Health Officer for many years and at one time in charge of Rockland County, showed his enthusiasm of the county unit system over the town and village health departments which now exist in most counties of New York State. Dr Slee demonstrated the value of organized nursing service in public health by its work in Westchester County. While the doctor did claim a county health unit to be more expensive than the present system, he feels that there is no comparison in its results.

The entertainment presented by Mr Francis R King was voted as the best ever presented at an Annual Banquet. The members of the Society had a very enjoyable and profitable afternoon.

WILLIAM J RYAN, *Secretary*

CLINTON COUNTY

The Clinton County Medical Society at its annual meeting on November 5th, elected the following officers for 1932:

President, Dr I S Haynes, Plattsburg, Vice-President, Dr I A Rowson, Plattsburg, Secretary, Dr A S Schneider, Plattsburg, Treasurer, Dr F K Ryan, Plattsburg, Delegate, Dr A S Schneider, Plattsburg, Alternate, Dr L F Schiff, Plattsburg, Censors

Drs G D Darc, W F Ladue, K M Clough.

At this meeting the committee on Public Welfare Charges reported the probability of securing an arrangement at a meeting of the County Supervisors, which was then in session, for the compensation of physicians taking care of indigent cases throughout the county of Clinton.

LEO F SCHIFF, *Secretary*

HERKIMER COUNTY

The 125th Annual Meeting of the Medical Society of the County of Herkimer was held Tuesday evening, Dec. 8th, in the Guild Room of Christ Episcopal Church in Herkimer, N. Y. The Annual Banquet, a delicious turkey dinner, was served by the Ladies' Guild at 6:30 P.M. and about 35 members of the society were present.

At the business meeting which followed, the matter of compulsory county health units was discussed; and while no specific action was taken, the consensus of opinion was that the previous action of this society in September, 1930, opposing the formation of compulsory county health units, be allowed to stand until the State Legislature rules otherwise.

A committee consisting of Doctors Sabin, Diss, and Santry was appointed to confer with the Herkimer County Board of Supervisors regarding amendments and revisions to the present fee bill.

A motion was carried that the society accept the gift of a safe from the widow of the late Dr. Ingham of Little Falls and that it be removed to the office of our Secretary, Dr. W. B. Brooks, at Mohawk, to be used by the society for the safeguarding of the records of the past 125 years.

The following officers were elected for the ensuing year: President, T. B. O'Neil, M.D.; 1st Vice-President, O. H. Love, M.D.; 2nd Vice-President, C. C. Whittemore, M.D.; 3rd Vice-President, Henry Field, M.D.; Secretary, W. B. Brooks, M.D.; Treasurer, A. L. Fagan, M.D.; Librarian, W. H. Petrie, M.D.; Censors: F. C. Sabin, F. H. Moore, Henry Field, J. L. Crofts, F. B. Conterman; for Delegate to N. Y. State Medical Society, T. B. O'Neil, M.D.; for Alternate, O. H. Love, M.D.

Doctors Aloisio and McDonald, both of Herkimer, were elected to membership in this society.

The retiring President, Dr. H. C. Murray, after thanking the members and committees for their cooperation during the past year, proceeded to the reading of his paper, "The Physician and the Public." He showed that the present day medical profession was being imposed upon, besieged and exploited for selfish gains by cultists, lay organizations, lay press, State legislatures, politicians, welfare organizations, free clinics, etc., and warned the members to be alert concerning such encroachments upon our rights. He also brought out the fact that apparent lack of ethics, petty jealousies and commercialism among the members themselves were harming the profession in the esteem of the public.

Doctors Love and Chattaway escorted the new President, Dr. T. B. O'Neil, to the Chair. Dr. O'Neil appointed the following committees to serve for the coming year:

Executive: Doctors O'Neil, Brooks, Murray, Sabin, Fagan, Conterman, Santry.

Membership: Doctors Albones, Diss, and Gallo.

Public Relations: Doctors Graves, Parkinson, Vickers, Barney, Albones.

Publicity: Doctors Sabin, Moore, and Conterman.

Legislative: Doctors Crofts, Fagan, C. G. Strobel, Eveleth, Jones.

Obituary: Doctors Love, Moore, and Jones.

Program: Doctors Love, Whittemore, Henry Field.

The meeting adjourned at 10:15 P.M.

F. B. CONTERMAN, *Publicity Committee.*

THE DAILY PRESS

DARWIN'S CENTENARY

The New York *Herald Tribune* of December 27, 1931, has a descriptive article on the one hundredth anniversary of the beginning of the scientific career of Charles Darwin. The writer says:

"On the 27th of December, 1831, the British surveying ship *Beagle* sailed for South America, with Charles Darwin, twenty-two years old, on board as naturalist. "The voyage of the *Beagle*," said Darwin in his autobiography, "has been the most important event of my life and has determined my whole career." Consequently it was one of the most important events in modern history—to be mentioned after battles and birthdays are forgotten. During those five years Darwin's main interests were established, his careful habits of observation were developed, and he began to brood over those basic questions which he afterward answered, for the approval or dismay of the world.

"Among the few books in the crowded cabin he shared with FitzRoy, Darwin had the first volume of Charles Lyell's 'Principles of Geology,' recently published. That work will never receive

its due from the general public, but it was epoch-making in geology, and it prepared the way for 'The Origin of Species.' From Lyell Darwin learned to interpret the past in terms of the present, to understand that the formation of the earth was the result of slow, gradual changes over vast periods of time rather than the result of Biblical catastrophes which took place within a few thousand years. The power of all-conquering time is easier to appreciate than the occasional finger of God."

The *Beagle* arrived in England on September 2, 1836, and Darwin spent the next few years in writing his observations. The newspaper article closes with the following paragraph:

"In 1838 Darwin read Malthus on the 'Principles of Population,' and only then did he have a key to the 'mystery of mysteries,' for if the birth rate increases more rapidly than the food supply, a ceaseless struggle for existence will ensue, leading to the 'appearance of new beings on this earth.'"

MEDICAL PUBLICITY

The effects of premature publicity are described in the following editorial in the New York *Herald Tribune* of December 27, 1931:

"A few weeks ago a Middle Western physician whom we leave nameless and unlocated to save him further trouble, had the somewhat doubtful good fortune to discover what may be a successful way of treating baldness with certain gland products. A conservative, carefully guarded and entirely proper notice of this fact was issued through the American Medical Association. One result the physician now writes to the association, is that he has received several thousand letters which he is totally impossible to answer. Commercial organizations interested in exploiting the supposed cure have besieged the unfortunate discoverer. Less scrupulous individuals have claimed to be associated with him. Undoubtedly he and his associates are greatly, and rightly, annoyed. All of which is an object lesson in why scientific men even outside the field of medicine and whose work

deals with matters of less insistent interest than the hair on the public's head, are acquiring grave distrust of publicity, as a sword with two sharp edges.

"Abundant publicity and corresponding public interest in scientific advances have been responsible no one doubts, for much of the present prosperity of scientific research in money and in men. It is inevitable that these boons like most others in this world, must be bought. The fear is that the price is too high, for more is likely to be paid than mere inconvenience like that of the bedeviled discoverer of the possible baldness cure. What happens to scientists, after all is not of any great importance, even, perhaps, what happens to science. Far more significant, no philosopher can doubt, is what happens to public thinking. Too much attention to science which is still raw and indigestible may easily result in new varieties of superstition under which clear thinking again may drown."

MODERN MAGIC

The New York *Times* of December 22, 1931 has the following comment on the reaction of modern man to ideas of magic:

"Slogans such as 'an apple a day keeps the doctor away' and admonitions to 'brush your teeth twice a day' are no more than modern survivals

of the magic of the primitive savage, who, when common sense failed him, fell back on amulets and talismen, according to Dr. Clark Wissler, anthropologist, who delivered the address as retiring president on 'the primitive background of civilization' at the annual dinner last night of the New York Academy of Sciences and affiliated societies at the Hotel Biltmore.

"The savage had his slogans, and we still have them in slightly different form. The savage used common sense on anything he could verify by experience. When common sense failed he resorted to magic. Thus he distinguished between being struck by a bear and being hit by lightning. For defense against the former he used practical

weapons. For defense against the latter he employed amulets. His slogan was: Put feathers in your hair and keep lightning away.'

"The savage attempted to build up interpretations of life and experiences, and we do the same. These attempts are divided into four groups of main ideas—common sense, magic, the supernatural and the aesthetic.

"As science and civilization progress, the common sense and aesthetic ideas grow stronger, while the magic and the supernatural elements grow weaker. But they are never fully eradicated and they lurk somewhere within us, buried a little deeper than before, but yet ready to assert themselves at the proper moments."

HEALTH AND BUSINESS DEPRESSION

The New York *Times* of January 5 has an editorial comment on the favorable showing contained in the annual report of the New York City Department of Health, saying:

"When the full record of the year 1931 is written, no chapter will be more striking than the one dealing with public health. The country was in the grip of the most serious industrial depression in a generation. No large area was exempt from its effects. Town and country, farmer and mechanic, East and West, North and South—all were affected. Everywhere poverty was accentuated. Family budgets had to be sharply reduced. Men and women skimped their own rations to provide for their children. The demands on charitable organizations were without parallel, coming often from families who never before knew the meaning of want. By all the signs and all the

precedents, hard times so seriously prolonged should have brought in their train disease and death. Actually, 1931 was one of the healthiest years in the history of the country.

"No one can say how long the present favorable health conditions will last. 'Sooner or later we must expect evidences of increased morbidity and mortality if the economic stringency is much prolonged,' Dr. Dublin warns. Nor is the other side of the picture to be ignored. Providence may be kind to man, but man is still ruthless enough in his dealings with his neighbor and himself. Murders and suicides reached an all-time peak in New York State last year, and in New York City the deaths resulting from automobile accidents exceeded those from typhoid fever, measles, scarlet fever, diphtheria, whooping-cough, cerebro-spinal meningitis and childbirth all combined."

ALMS-GIVING

The laws of both the State and the City of New York forbid public begging; and yet the practice is openly carried on. The New York *Times* of January 5 makes the following editorial comment on the warning and advice issued by the Welfare Council of New York City:

"Any one can easily satisfy himself that no needy person, man or woman, must beg in the streets for food or lodging. There are available more beds and more free meals than have yet been required. On the coldest nights this Winter hundreds of beds have been unused and facilities for serving warm food indoors have not thus far been fully used. Within an hour the homeless man asking for food and lodging at the Central Registration Bureau at South Ferry has both. If he happens to be nearer to one of the forty offices cooperating with the central bureau, he can

get what he needs quickly. The full list of agencies was published in yesterday's *Times*.

"The Welfare Council is opposed to giving away meal and bed tickets as well as to the indiscriminate handing out of cash. Many suggestions for books of such tickets, to be carried by citizens who are asked for alms, have been made and some have been tried. The Welfare Council has discovered that any such plan provides an incentive for begging. Tickets are used for money in card and dice games, and three nickel tickets sell among men on the Bowery for a dime. One who feels that he does not condone begging when he gives a meal ticket is in reality encouraging it. If instead he directs the beggar to the nearest agency of the Welfare Council, the man will be cared for, not only with an immediate meal, but until he is able to provide for himself."

BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.

A THOUSAND MARRIAGES. A Medical Study of Sex Adjustment. By ROBERT LATOU DICKINSON and LURA BEAM. Octavo of 482 pages, illustrated. Baltimore, The Williams & Wilkins Company, 1931. Cloth, \$5.00. (Medical Aspects of Human Fertility Series, issued by the National Committee on Maternal Health, Inc.)

ESSENTIALS OF PSYCHIATRY. By GEORGE W. HENRY, A.B., M.D. Second edition. Octavo of 304 pages. Baltimore, The Williams & Wilkins Company, 1931. Cloth, \$4.00.

SURGICAL CLINICS OF NORTH AMERICA. Vol. 11, No. 5, October, 1931. (Pacific Coast Surgical Association Number.) Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues). Cloth, \$16.00 net; paper, \$12.00 net.

PREPARATION OF SCIENTIFIC AND TECHNICAL PAPERS. By SAM F. TRELEASE and EMMA SAREPTA YULE. Second edition. 12mo of 117 pages. Baltimore, The Williams & Wilkins Company, 1930. Cloth, \$1.50.

CHILD HEALTH AND THE COMMUNITY. An Interpretation of Cooperative Effort in Public Health. By COURTNEY DINWIDDIE. Octavo of 80 pages, illustrated. New York, The Commonwealth Fund, 1931. Cloth, \$1.00.

HOW'S YOUR BLOOD PRESSURE? By CLARENCE L. ANDREWS, M.D. Octavo of 225 pages. New York, The Macmillan Company, 1931. Cloth, \$2.50.

THE MEDICAL RECORD VISITING LIST OR PHYSICIANS' DIARY FOR 1932. Revised. 16mo New York, William Wood & Company, [1931]. Flexible Cloth, \$2.00.

PHANTASTICA NARCOTIC AND STIMULATING DRUGS. Their Use and Abuse. By LOUIS LEWIN. Octavo of 335 pages. New York, E. P. Dutton & Company, 1931. Cloth, \$3.75.

THE CONQUEST OF OLD AGE. Methods to effect rejuvenation and to increase functional activity. By PETER SCHMIDT, M.D. Translated by EDEN and CEDAR PAUL. Octavo of 307 pages, illustrated. New York, E. P. Dutton & Co., Inc., 1931. Cloth, \$5.00.

RECLAIMING THE DRINKER. By CHARLES B. TOWNS. 12mo of 77 pages. New York, Barnes & Company, [c.1931]. Cloth, \$1.00.

MEDICAL CLINICS OF NORTH AMERICA. Vol. 15, No. 3, November, 1931. (Chicago Number.) Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues). Cloth, \$16.00 net; paper, \$12.00 net.

APPLIED PHYSIOLOGY. By SAMSON WRIGHT, M.D., M.R.C.P. Fourth edition. Octavo of 552 pages, illustrated. New York, Oxford University Press, 1931. Cloth, \$5.50. (Oxford Medical Publications.)

THE GREAT PHYSICIAN. A Short Life of Sir William Osler. By EDITH GITTINGS REID. Octavo of 299 pages, illustrated. New York, Oxford University Press, 1931. Cloth, \$3.50.

CRITERIA FOR THE INTERPRETATION OF ELECTROCARDIOGRAMS. Prepared with the aid of the Committee on Research of the Heart Committee by ARTHUR C. DE GRAFF, M.D. 12mo of 13 pages, illustrated. New York, New York Tuberculosis and Health Association, Inc., 1931. Paper, 35c.

GUIDE TO RADIOLOGIC DIAGNOSIS IN HEART DISEASE. Prepared with the aid of the Committee on Research of the Heart Committee by GEZA NEMET, M.D. 12mo of 25 pages, illustrated. New York, New York Tuberculosis and Health Association, Inc., 1931. Paper, 35c.

INTRODUCTION TO THE HISTORY OF SCIENCE. By GEORGE SARTON. Two volumes in two parts, from Rabbi Ben Ezra to Roger Bacon. Quarto of 1251 pages. Baltimore, The Williams & Wilkins Company, 1931. Cloth, \$12.00. (Carnegie Institution of Washington Publication No. 376.)

EMERGENCY SURGERY. By JOHN WILLIAM SLUSS, A.M., M.D., and JOHN WALTER MARTIN, M.D., F.A.C.S., and CAMILIUS BOWEN DEMOTTE, B.D., M.D. Fifth edition. 12mo of 879 pages, illustrated. Philadelphia, P. Blakiston's Son & Co., Inc., 1931. Flexible cloth, \$5.00.

A SURVEY OF THE MEDICAL FACILITIES OF SAN JOAQUIN COUNTY, CALIFORNIA. 1929. By NATHAN SINAI, D.P.H. Octavo of 214 pages. Chicago, The University of Chicago Press, [c.1931]. Paper, \$1.00. (Publications of the Committee on the Costs of Medical Care: No. 12.)

THE SURGICAL CLINICS OF NORTH AMERICA. Vol. 11, No. 6, December, 1931. (Philadelphia Number.) Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues): Cloth, \$16.00 net; paper, \$12.00 net.

THE VITAMINS. By ETHEL BROWNING, M.D. Quarto of 575 pages, illustrated. Baltimore, The Williams & Wilkins Company, 1931. Paper, \$10.00. (Monographs of the Pickett-Thomson Research Laboratory, Volume 1.)

THE HUMAN VOICE: ITS CARE AND DEVELOPMENT. By LEON FELDERMAN, M.D. 12mo of 301 pages, illustrated. New York, Henry Holt and Company, [c.1931]. Cloth, \$2.50.

A NON-SURGICAL CONSIDERATION OF PROSTATIC ENLARGEMENT: Including a lecture on The Myth of the Bladder Neck Bar. By EDWIN W. HIRSCH, M.D. Octavo of 79 pages, illustrated. St. Paul, Minn., Bruce Publishing Company, 1931. Boards, \$2.00.

HANDBOOK OF SKIN DISEASES. By FREDERICK GARDINER, M.D. Third edition. 12 mo of 283 pages, illustrated. New York, William Wood & Company, 1931. Cloth, \$3.50.

MODERN MEDICAL TREATMENT. By E. BELLINGHAM-SMITH, M.D., F.R.C.P., and ANTHONY FEILING, M.D., F.R.C.P. Two volumes. Octavo of 1406 pages, illustrated. New York, William Wood and Company, 1931. Cloth, \$12.00.

BOOK REVIEWS

RECENT ADVANCES IN THE STUDY OF THE PSYCHONEUROSES. By MILLAIS CULPIN, M.D., F.R.C.S. Octavo of 348 pages. Philadelphia, P. Blakiston's Son & Co., Inc., 1931. Cloth, \$3.50. (The Recent Advances Series.)

As the name of this book indicates, the author presents the modern advances in the study of the psychoneuroses.

The first chapter is a historical review including the contribution of Charcot and Freud to our knowledge. There then follows a discussion of the psychoneuroses of war. This leads to a presentation of the author's conception of the present position of psychoanalysis with which he is extremely sympathetic.

In the last two chapters of the book the author discusses the psychology of childhood and the set-up of a psychotherapeutic clinic. He traces the development of interest in child behavior during the post-war years, with the establishment of child guidance clinics.

This book is of value to the physician interested in keeping up in a general way with the recent advances in the psychoneuroses. STANLEY S. LAMM.

MEDICAL ADMINISTRATION OF TEACHING HOSPITALS. By EMMET B. BAY, M.D. Octavo of 136 pages. Chicago, The University of Chicago Press, 1931. Cloth, \$2.00. (Medical Economics Series.)

Medical schools utilize clinical material in affiliated hospitals for student instruction. Dr. Bay submits a carefully prepared report of an investigation of medical administration in nineteen hospitals connected with medical schools. The extent and manner of utilization of clinical material in hospital and out-patient departments for teaching purposes by the affiliated schools has been studied, and, as far as possible, made the subject of total and comparative study.

This report, in one small volume of 130 pages, is one of a group of studies known as the "Medical Economics Series," under the capable editorship of Dr. Michael M. Davis. Its preparation and issue was made possible through a grant from the Rockefeller Foundation.

An approach to this excellent study is set forth in the opening paragraph in Chapter XIII and could well have been included in the introduction:

- (1) To present as clearly as possible the many different problems which arise in medical administration; and
- (2) To develop a technique for studying administrative matters in such (teaching) hospitals.

The author, in his foreword, "hopes the following pages will contain some of the elements to interest others in this field." To engender such interest, the following quotation is a challenge to the hospital administrator:

"Hospital superintendents were found to be too absorbed in the management of their large physical plants and the non-professional personnel, and too influenced by the community purposes of many teaching hospitals, to have much interest in or knowledge of the teaching and research functions of their institutions." If this were not enough to engage our attention, he concludes:

"Under such circumstances it is obvious then that some other administrative officer must carry the supervision of these activities."

This observation, based upon facts submitted with the report, challenges the consideration of governing boards of hospitals and their administrators wherever clinical material is utilized for teaching purposes.

One arrives at a very definite conclusion as to the medical administrator of the future. Where teaching of

medicine depends on the clinical opportunities of the affiliated hospital, it is clearly shown there must be strong, vigorous representation of the needs of the medical school to secure cases in kind and quantity to meet its requirements. If the hospital administrator envisions these needs, if he exhibits a sympathetic cooperation in meeting them fairly and impartially no additional administrator is needed. Failing to secure satisfactory consideration, the medical school is forced to protect its interests in securing adequate clinical facilities through representation primarily responsible to it.

Those interested in the clinical aspects of medical education, both undergraduate and graduate, will find this book interesting. It is not dry, and will cause the reader to pause, think, and possibly stimulate to further study. It will at least urge the introspective hospital administrator to ponder. JOHN E. DAUGHERTY.

TEXT-BOOK OF HISTOLOGY for Medical and Dental Students. By EUGENE C. PIETTE, M.D. Octavo of 466 pages, illustrated. Philadelphia, F. A. Davis Company, 1931. Cloth, \$4.50.

The subject matter of this book is presented in a brief style. The essentials of histological technique are given in a short chapter of about fifteen pages. This is followed by another short chapter on cytology. The following five chapters are devoted to general histology and fourteen chapters to special histology.

Nothing new or original in histology is presented in this work. Original illustrations are very scarce. There are numerous excellent illustrations carefully selected from the well-known works of authors such as: Schafer, Stöhr-Möllendorff, Gurwitsch, Böhm-Davidoff, Triepel, Schmaus-Herxheimer, Landois and others.

Being partly intended for the dental student, the author dwells at relatively fair length, on the subject of Teeth, which phase, some other text-books on histology tend to neglect. SILIK H. POLAYES.

MODERN PROCTOLOGY. By MARION C. PRUITT, M.D., L.R.C.P. Octavo of 404 pages, illustrated. St. Louis, The C. V. Mosby Company, 1931. Cloth, \$8.00.

In this volume of 404 pages with 233 illustrations the author—according to his preface—aims to present a concise, yet comprehensive text-book on proctology, for the student and busy practitioner. As such, it is a welcome additional contribution to our fast growing literature on diseases of the Colon, Rectum and Anus.

This comparatively recently recognized medical specialty, has been gaining an ever-growing number of adherents among the general practitioners. They are beginning to recognize, that the diseases of the Rectum and Anus neither deserve to be treated lightly, nor to be relegated to the care of the irregular practitioner, as it has been customary heretofore. But, in order to successfully compete with the quack, the physician must possess an up-to-date knowledge in the treatment of these diseases and this is the reason for the author's issuing of the book, in order to include in it the most recent advances made in this field.

The author follows the orthodox arrangement and division of his book into chapters, beginning with anatomy, methods of examination, anesthesia and following with chapters on specific diseases. In discussing the various operative procedures, the author is objective in his method, presenting a fair and accurate description of the respective methods employed by different authorities. The illustrations in the book—the diagrammatic as well as the photographic—are very illuminating, and

facilitate the reader's understanding of the pathology or operative technique. Among the newer methods of treatment the author includes four methods of electric treatment of Hemorrhoids, the injection treatment of Pruritis Ani and the vaccine treatment of Ulcerative Colitis.

It is a well written and instructive book and is a distinct contribution to Proctologic literature.

MICHAEL CANICK.

CUTANEOUS X-RAY AND RADIUM THERAPY. By HENRY H. HAZEN, A.M., M.D. Octavo of 166 pages, illustrated. St. Louis, The C. V. Mosby Company, 1931. Cloth, \$3.00.

It is indeed surprising that so small a book as this gives one the feeling that the subject of X-Ray and Radium therapy of the skin has been rather completely covered. The author has given the history of both the X-Ray and Radium, described the apparatus, given the estimation of dosage and dealt with the technique of administration. He has considered the action of these agents upon the normal and diseased skin, and, finally, after a résumé of their effect on various diseases he has discussed these diseases individually, describing the intensity of the single treatment and the number of treatments permissible within the zone of safety.

The book leaves little else to be said except the dis-
courses on the many theoretical problems facing the dermatological therapist, and is well worth possessing.

E. ALMORE GAUVAIN.

A TEXT-BOOK OF PATHOLOGY. By FRANCIS DELAFIELD, M.D., LL.D., and T. MITCHELL PRUDEN, M.D., LL.D. Fifteenth edition, revised by FRANCIS CARTER WOOD, M.D. Octavo of 1339 pages, illustrated. New York, William Wood and Company, 1931. Cloth, \$10.00.

In the 15th edition of the Text-Book of Pathology by Delafield and Prudden, edited by Francis Carter Wood, the original edition of this work has almost completely lost its identity because of the tremendous increase in knowledge in tissue pathology since that first edition was published.

The present edition consists of three parts: the first of which is devoted to general pathology; the second to special pathology, and the third to post-mortem technique. The field is very well covered although the individual subjects are treated tersely and briefly. This must be expected, however, in a work which covers so much ground and is intended mainly for students. A number of subjects, such as immunology and parasitology are included. The space devoted to these may have been better utilized for more detailed discussion of pathology itself. Over 800 illustrations, very clearly and comprehensively amplify the texts. Many of them are new and depict the pathology in an unusually excellent way. The section on post-mortem technique is complete. The procedure is described as carried out by the author and therefore is not to be viewed too critically. A mass of references to outstanding articles on the various subjects are incorporated.

As a whole, the work reflects the excellent standard set by Delafield and Prudden and serves to carry on the tradition of these noted pioneers. The book as a whole can be highly recommended to both students and practitioners as an exceedingly valuable text-book for the study of pathology.

MAX LEDERER.

COMMUNICABLE DISEASE CONTROL. Report of the Committee on Communicable Disease Control, George H. Bigelow, M.D., Chairman. White House Conference on Child Health and Protection, Octavo of 243 pages. New York, The Century Co., [c.1931]. Cloth, \$2.25.

This committee seems to have found that its duties might be quickly and well done by recommending that

the various cities and states adopt and live up to the program of the American Public Health Association as expressed in the "Handbook" of the Association. Comparative morbidity, mortality and case fatality tables are included to prove the universal success in Smallpox, Diphtheria and Typhoid prevention and the need for more painstaking application of Quarantine and Isolation to lower the fatality of Whooping Cough and Measles in the younger age groups. The chapter devoted to the definition of terms used to designate various control procedures is illuminating. For example, Quarantine is now used to mean the limitation of the freedom of movement of human or animal contacts for a period equal to the longest usual incubation period of the disease; whereas Isolation means the limitation put upon the movements of the sick person or carrier. Individually tabulated are the advised control measures in fifty-two communicable diseases, excellent for ready reference to standard practice. We learn that fumigation has been generally abandoned and that placarding is rapidly being discarded. Where good medical supervision of school children obtains, selective quarantine is increasing the freedom of movement of adult contacts who are probably immune to children's diseases and of immune contacts among the children; the loss of schooling is being reduced by allowing non-immune contacts to continue at school until a day or two before the expected onset of prodromes especially in the milder diseases like German Measles, Chickenpox and Mumps in which the incubation period is relatively long. The usual plea is made for better trained Doctors of Public Health, better salaries for them, well-staffed laboratories, more public health nurses for follow-up work, better standardization of the laws governing reporting, minimal quarantine and isolation periods, and finally for gradual education of the governing bodies and of the people in general so that the laws may be more effectively enforced. In general the publisher has done everything possible to make the book easily readable and interesting. Very little attention has been given to the General Practitioner's part in control and in some places the English construction is awkward. The index is well done.

KENNETH G. JENNINGS.

A CLINICAL STUDY OF ADDISON'S DISEASE. By LEONARD G. ROWNTREE, M.D., and ALBERT M. SNELL, M.D. 12mo of 317 pages, illustrated. Philadelphia and London, W. B. Saunders Company, 1931. Cloth, \$4.00. (Mayo Clinic Monographs.)

In the foreword of this excellent study we find the following statement, "We often marvel at those physicians who, only a few decades ago, were so capable in the art of medicine that they could make a diagnosis of an obscure disease almost without accessory aids. In 1855 Thomas Addison was able, with great accuracy, to describe a syndrome of disease of the suprarenal glands." The authors give a review of the scant knowledge of the suprarenal glands before the time of Addison's description of the disease which he believed due to pathology in the suprarenal glands. So valuable and accurate is this description clinically and at post-mortem examination, as given by Addison that the authors state, "Because of its great intrinsic value and its relative inaccessibility this article is presented in full."

A study of 117 patients having Addison's disease is presented in this volume. Thirty-three of these patients were examined post-mortem. The histories, symptoms and physical findings of all of the patients are given in detail, and a careful review of all this data is made. This volume will well repay a careful study as it is one of the most complete works on the subject ever presented. It has been carefully prepared, is well written, with excellent tables, diagrams and figures, and presented in the best manner of the publishers.

HENRY M. MOSES.

OUR NEIGHBORS

CONFERENCE OF COUNTY SECRETARIES IN NEW JERSEY

The December Journal of the Medical Society of New Jersey contains a fifteen-page account of the seventh annual conference of the secretaries and reporters of the county medical societies of the State; held in Trenton on November 4, 1931, with twelve counties represented and a total attendance of twenty-six. This proportion of attendance is about the same as that at the New York Conference. (See this Journal, October, 1931, page 1221.)

The general topic of discussion was "Publicity and Advertising." Dr. John F. Hagerty, President of the Medical Society of New Jersey, introduced the subject, and said:

"This meeting is intended to lead the profession into a discussion of the advisability of advertising what organized medicine has accomplished, and I think we are fully justified in proclaiming to the world the aims of scientific medicine. If we just recall the countless thousands of lives that have been saved, the millions of dollars worth of property salvaged; and if we reflect a minute upon the sum total of human misery that has been alleviated, I think we are amply justified in proclaiming those facts to the public and in looking to the public and to the legislators for approval of any steps that we might wish to take."

Dr. Edward G. Waters of Jersey City presented a plan for periodic health examinations which involved some radical changes in publicity by county societies. The plan is described in four sections as follows:

"1. The adoption of a form of procedure for periodic physical examinations with delineation of minimum requirements for the examining doctor to meet.

"2. The adoption of a standard fee for the community. It must be unalterable by the physician and include all that the standard form of procedure delineates. In addition, there must be definitely known charges for any additional examinations, such as x-rays and blood chemistry, and these must be compatible with the scale of charge for the entire examination.

"3. Publication of a list of members of the County Society of the district, indicating those members willing to give the examination at the standard fee.

"The public must be apprised of the adoption of such a plan, and must know what physicians are available for making examinations. To avoid any possibility of confusion as to

medical standing, the entire roster of the county society—which means the roll of men acceptable to the medical brotherhood—should be published. However, as plan-acceptance is elective with our Society members, such published lists should clearly indicate those men who are willing to make health examinations, as contrasted with men in good standing who neither subscribe to the form of procedure nor the standard fee.

"Publication of such lists will prove of material assistance to the county societies. The public will be enabled to ascertain the identity of medically eligible men. Many able practitioners who for various reasons do not join their county's society will be forced to do so to maintain their professional standing in the eyes of the public. Illegitimate practitioners will find the going harder, and twilight practitioners will be refused the light of community acceptance. A reference list of competent physicians will be available in emergency. Physicians will profit individually and as a group, for an ethical type of advertising is then available. The public will profit vastly from the opportunity to distinguish the medically acceptable from those who are not, and through elimination of the undesirables in medicine.

"4. Publication of the detailed form of procedure. The public at large does not know what a complete medical examination means. The average person knows that for a cold his chest is examined, and for a sore throat his nose and throat are gone over, but he has seldom, if ever, gone to his physician for a complete examination when he was not sick. This fact doubtless accounts in large measure for the reputation of completeness and thoroughness acquired by lay-controlled clinics specializing in health examinations. A patient visiting the office for treatment of a head cold, or sebaceous cyst of the scalp, would think it very queer if the doctor tested the ocular movements and reflexes, took the height and weight, looked in the ears, tried the patellar reflexes, and so on; but the same patient, subsequently taking a routine physical examination at a clinic specializing in such examinations, would doubtless widely advertise the thoroughness of the going-over he received.

"When the examination is completed, the patient should be given a written report on the

(Continued on page 110—Adv. xii)

FOR CONVENIENT RELIEF OF NASAL CONGESTION . .

While the Chinese drug Ma Huang has been used for centuries, the value of ephedrine—its active alkaloid—has only recently become known. Investigation has shown that it is effective in the treatment of nasal congestion.

CAPSULES EPHEDRINE COMPOUND SQUIBB contain ephedrine oleate in combination with aromatic oils and preservatives in a petrolatum base.

CAPSULES EPHEDRINE COMPOUND SQUIBB

are supplied in convenient boxes of one dozen and can be used anywhere at any time. These flexible, long-necked gelatin capsules provide a simple, effective means of applying ephedrine without the use of an atomizer.

For further information concerning CAPSULES EPHEDRINE COMPOUND and other Squibb Ephedrine products, write to the Professional Service Department, E. R. Squibb & Sons, 745 Fifth Avenue, New York City.

CAPSULES EPHEDRINE COMPOUND SQUIBB

DIGITALIS

ADOPTION OF AN INTERNATIONAL ASSAY STANDARD

WITH a view to promoting a more accurate method of standardizing digitalis, the Frankfurt Conference of 1928 proposed: "That when the dosage of digitalis or its preparations is expressed in units of activity, the unit employed for any preparation *and in any country* should be an international unit, which should be defined as the specific activity contained in 0.1 gramme of the International Standard Powder."

Since 1928 a powder equal in strength to the international Digitalis Powder has been used as an official standard in Germany.

Adoption of the international standard has likewise been recommended by the French Codex and the Sub-Committee on Digitalis of the British Pharmacopœia.

In the belief that the international unit provides the clinician with greater uniformity of strength, Upsher Smith are pioneering this method of standardization.

We now put one international unit of digitalis in one cc. of tincture and in one capsule or tablet. Note how this simplifies dosage:

- 1 International Unit = 2 grains U.S.P. Digitalis Powder
- 1 cc. Tincture = 2 grains U.S.P. Digitalis Powder
- 1 International Unit Capsule = 2 grains U.S.P. Digitalis Powder
- ½ International Unit Tablet = 1 grain U.S.P. Digitalis Powder

Full information on the International Unit is supplied in our new booklet, "New Thoughts on Digitalis Action and Dosage."

Write for your copy today and for clinical trial package of Upsher Smith Digitalis.

(Continued from page 108)

examination, with notation of defects which require attention. The detailed record of the examination is to be held and filed by the examiner. However, if the patient decides to take treatment elsewhere, a copy of the complete record of the examination must be forwarded to the doctor treating that patient should he request it. This is proper and ethical and cannot fail to materially increase confidence in our efforts along these lines."

The discussion was confined to a motion, which was carried, to invite Doctor Waters to present the plan to the State Society. Dr. H. J. Perlberg, of Jersey City, described the same publicity done in Hudson County, as follows:

"Hudson County, during the past spring, waged a vigorous and, we believe, a successful campaign for prophylactic diphtheria inoculations using the press by means of paid advertisements. The newspapers helped along by frequent editorials. A special rate of \$6 for the 3 inoculations was agreed upon by the members of our society, and immunization was so advertised. I know that the response was most encouraging. We now intend to go ahead on a plan of boosting periodic health examinations, each to be made by the patient's own private physician. We believe that this should also prove successful, but it must be borne in mind that the patient must receive a bona fide examination, and not a cursory physical inspection. Permit them to learn the difference between a hurried, slipshod looking over and a really competent, physical examination, from head to toe-nails, and the people will remain or become our friends, instead of regarding us with suspicion, as is often the case nowadays."

Dr. J. M. Kuder, of Mount Holly, described the medical publicity conducted by the Burlington County Society, through its Committee on Public Relations and Information:

"This Committee is prepared to furnish a speaker at any time, at any place, on any question of public health, or any reasonable request, made by any responsible lay organization presented to the secretary of the society. Furthermore, this committee is promulgating a series of free public lectures on health matters, to be given during the coming autumn and winter months, by members of the Burlington County Medical Society, in as many towns and communities throughout the county as shall express a desire to have such a series of lectures. It is our endeavor to educate the public to look to the County Medical Society as headquarters for health information.

(Continued on page 111—Adv. xiii)

(Continued from page 110—Adv. xii)

"In the Burlington County Medical Society, the agency which we have employed with very gratifying results has been the Woman's Auxiliary to the Medical Society. These women, as loyal as a group to our organization as they have been to us individually in our private practices, should receive no small credit for the encouraging prospects which we anticipate. Through the ramifications of their personal and individual interests in civic and social organizations, and frequently their identification with program committees, these women have been able to place members of our local society, as speakers on health subjects, on the programs of many lay organizations. This has paved the way for wider publicity, and now requests for similar talks are coming in independently of the efforts of the Auxiliary; so that the increase in requests is multiplying in geometric rather than arithmetic progression.

"Our county society has also been fortunate in being able to bring its message of health education before Rotary Clubs, Y's, Men's Clubs, and other service organizations.

"Our county is wide in extent and but sparsely populated. It contains no metropolitan center. It possesses but one community of wealth. We have but a few dozen members in our medical society. We have no funds to finance broadcasting, to purchase publicity space, to placard communities. All the cooperation we receive must come from the hearts and intelligence of the people. And perhaps our satisfaction is not entirely unmixed with a little pardonable pride, in that our publicity has been attained without an appeal to agencies of publicity through their purses, but perhaps through their conviction that the service which we are rendering is above price.

PRESS PUBLICITY IN FLORIDA

The December number of the Journal of the Florida Medical Association, Inc., contains a report on press publicity made by the Public Relations Committee of the State Association:

"There have been approximately twenty papers handed in of about 400 words each, for press publication. It was moved by Dr. McEwan and seconded by Dr. Holden that these articles start in the press at once. Passed. The secretary was instructed to arrange them in chronological order and send them to the Business Manager of the Journal for release as per his arrangements. The time when these articles should appear was thoroughly discussed. Moved by Dr. Irwin and seconded

(Continued on page 112—Adv. xiv)

"It is axiomatic that no one is immune to lawsuits."

COURTS AND DOCTORS

BY
LLOYD PAUL STRYKER

Formerly General Counsel for the Medical Society of the State of New York

The author is particularly well qualified to write this book because of his recognized ability as trial counsel and the experience gained by years of successful handling of mal-practice suits against doctors.

DR. CHARLES GORDON HEYD, President-Elect of the Medical Society of the State of New York, says in the preface, "The book should not only be owned but read by every doctor as a means of informing himself as to his inherent rights and privileges, and the conditions under which he might invite a suit; and finally, for the sane advice that the author has been able to present by example and precept, whereby a physician may, in a measure, protect and fortify himself against shameless attacks upon his professional conduct, art and skill . . . I heartily recommend it to my colleagues of the medical profession."

by Dr. McEwan that the articles should appear in the Sunday editions insofar as possible. These articles, therefore, would leave the business manager's office on or before the Wednesday preceding the Sunday of publication. Passed."

"This committee is not functioning for one month or one year, but it is laying the ground work for functioning on a much larger scale, as time goes on, for some years in the future. At present, we are doing the ground work, and literally re-writing and fitting articles to our own Florida needs from articles that have been previously used, largely by the Illinois State Society. It is indeed a kindness for these component states to thus enable Florida to make a better start by using their articles and their experience of years back. These articles, however, will soon be exhausted, and Florida must build up her own library and use her own articles, so that we can function independently and so that we can be in a position to help other State societies from time to time, as the States now functioning have helped us. With this end in view, we now request all county societies to send in articles, however short or long, that are of interest to the medical profession, which have appeared in their local society meetings, or which have been broadcast over local radio stations. These articles, that can be collected from the past, will be appreciated and the articles and talks that appear from time to time in the future should be sent in by the county society secretary to Dr. Wells, Daytona Beach, so that he may arrange them in their proper position, and thus keep up the sequence of press articles for the months and the years to come.

"Three local radio broadcasting stations report as follows: Orlando is broadcasting every Tuesday and Thursday at 11 A.M.; Tampa has started; Miami started the week of December 7, 1931."

CHIROPRACTIC IN MASSACHUSETTS

The *New England Journal of Medicine* of October 29, 1931, contains the following editorial description of a proposed attempt of the chiropractors to get recognition by means of an initiative petition:

"A recent item in the daily press reported that the chiropractors were about to file an initiative petition seeking passage of a law for the establishment of a state board of registration in chiropractic. It is suggested in the report that the board would consist of three persons to be appointed by the Governor to

(Continued on page 114—Adv. xvi)

DETOXIFICATION

A Clinical Fact

WHEN confronted with one of those indefinite toxemias as manifested by headache, vertigo and general malaise—where you feel certain that the condition is due to an absorption of toxin from the intestinal tract—is it not reasonable to expect relief from intestinal detoxification?

Larson, through the discovery of the detoxifying properties of sodium ricinoleate, and Morris and Dorst by their demonstration of the practicability of detoxifying the intestinal tract, have offered to the medical profession a new solution of the problem of intestinal toxemia.

The detoxifying principle, sodium ricinoleate, has been made available for clinical use under the name Soricin—offered in two forms—Soricin Capsules and Soricin Surgical Solution.

Soricin Capsules administered orally detoxify the content of the bowel, preventing the absorption of this material from the enteric tract.

Soricin Surgical is intended for colonic irrigation—to clean out the colon and to detoxify it. This is recommended in stubborn cases in conjunction with Soricin Capsules by mouth.

In administering Soricin Capsules it is important that they be given in cold water, and on an empty stomach, about one-half hour before meals.

The average dosage of Soricin Capsules is three to four 10-grain capsules daily during the first week or two, and followed by three to four 5-grain capsules over the balance of treatment. THE WM. S. MERRELL COMPANY, CINCINNATI, OHIO

(Continued from page 112—Adv. xiv)

pass upon the qualifications of applicants desiring to practice as chiropractors. The qualifications required were a preliminary 'equivalent of a high school education and to be grounded in the subjects of physiology, anatomy, chemistry, symptomatology, hygiene, sanitation, pathology and chiropractic analysis. The measure also provides that the applicants are to be graduated from a reputable chiropractic school giving a course of twenty-two hundred daylight hours'.

"Article 48 of the Constitution defines the difference between an initiative and a referendum. The former is an attempt to have new legislation referred on a ballot to the voters for their approval or disapproval, whereas a referendum is an attempt to change an existing law by the same method. An initiative petition must first be submitted to the attorney-general and must be signed by ten or more registered voters. If this subject has not been presented to the voters for at least three years and the signatures are those of registered voters, it is accepted by the attorney-general as proper material and the petitioners are so notified. This petition with the signatures of twenty thousand registered voters must be

placed in the office of the Secretary of State before 5.00 o'clock on the first Wednesday in December. Not more than five thousand signatures may be obtained in any one county. The bill then goes before the next session of the Legislature and, if accepted by it, goes on the ballot. If the action is adverse, five thousand more signatures must be obtained and submitted to the Secretary of State's office before the first Wednesday in August. It would then be legally approved and the initiative placed upon the official ballot in November.

"There has been but one standard for the qualification of fitness to practice the healing art in this Commonwealth, namely, passing the examinations given by the Board of Registration in Medicine. This method has been acceptable to the Homeopaths, Osteopaths and members of the regular school of medicine. It would be a definite step backward to change this policy. The official stamp of approval is thus placed upon every legalized practitioner of medicine in the State of Massachusetts; and, if a minor or a stranger calls a registered physician in an emergency, the public realizes that that physician has been examined and authorized to alleviate suffering and cure disease."

Colloidal IRON in ANEMIAS

Prescribed in
8 oz. bottles

Dose,
dr. i. t.i.d. p.c.

IDOZAN is a stable colloidal iron solution, NEUTRAL, and contains 5% of iron.

Colloidal iron therapy represents a significant advance over the old iron preparations.

IDOZAN is an active iron preparation which will produce a definite rise in the hemoglobin in cases of simple anemia, chlorosis, secondary anemia and post partum hemorrhage.

IDOZAN makes "new blood," better blood; thus acting as a dependable "iron tonic."

PUBLIC HEALTH PRACTICE IN ARKANSAS

The December issue of the Journal of the Arkansas Medical Society contains the following report of a subcommittee of the Council of the State Society; which was adopted by the Council:

"At the Texarkana meeting of the Arkansas Medical Society a subcommittee of the Council was appointed to investigate the activities of the County Health Units of the State Board of Health, including those of the County Health Officers and County Health Nurses, and report back at a subsequent meeting of the Council.

"Much objection was found to the activities of the health agencies. The activities objected to may be briefly stated as follows:

"1. The free immunization of large numbers of people against typhoid and diphtheria without attempting to differentiate between those able and those unable to pay for such services.

(Continued on page 117—Adv. xix)

(Continued from page 116—Adv. xviii)

"2. The activities of unsupervised County Health Nurses.

"3. The practice of curative medicine by full-time salaried health officials.

"4. The conducting of tonsil-removing and other clinics without consultation with physicians resident in the locality where the clinics are held.

"Of these, the greatest part of the objection was to the immunization program, and a minor part to the actual practice of medicine by health officers and nurses, and the manner in which the clinics were conducted. In fairness to the health authorities it was found that in certain counties the health work has been approved by the county medical society.

"The causes for the objections to the health activities may be briefly summarized as follows:

"1. Physicians feel that everything pertaining to the health, public or personal, of the community in which they reside and practice should be within the sphere of their activities, and that preventive and curative medicine should not be practiced without their knowledge, cooperation, and consent.

"2. Physicians believe that the examination of school children and other persons for physical defects and the administration of immunizing substances are a part of the practice of medicine and should not be done by a nurse or other unlicensed person.

"3. Physicians believe that providing medical services of any kind for persons able to pay for such services is an injustice and should not be permitted."

The Council adopted the following recommendations:

"1. Public health programs can be better carried out with the cooperation of the medical profession and the health authorities than with the antagonism or non-support of the physicians. For this reason, we believe that plans should be perfected by the Board of Health whereby the physicians of the different counties may, if they wish, have active participation in any health program that is instituted. We believe that the physicians can be utilized in the examination of school and pre-school children for remedial physical defects. We would recommend that, in those counties where objection has been raised to the wholesale immunizations by health nurses, this work be done by the physicians.

"2. Your committee would recommend the retention of the health nurses in those communities in which they are already at work, and that plans be instituted for securing nurses where there are none now. We believe that the services of the nurses will be invaluable in a cooperating health program. By defining the activities of the nurses so that there will

When decalcification occurs during pregnancy

IT IS important to warn expectant mothers of the danger of calcium deficiency during pregnancy. For unless there is sufficient calcium to take care of the developing fetus, there will be a withdrawal of calcium from the maternal structures—resulting, among other things, in rickets, soft bones, and carious teeth.

Does this sound like a bad thing?

in itself is an essential source of calcium.

Recommend this delicious chocolate flavor food drink to expectant mothers. Not only does it contain Vitamin D—not only does it add 70% more nourishment to milk—not only is it tempting to finicky appetites—it supplies extra body-building proteins, carbohydrates and minerals so essential to the mother and to the coming child.

Recommend Cocomalt to your young patients, too. They'll love it. Cocomalt is high in concentrated food value—low in cost. At grocers and leading drug stores— $\frac{1}{2}$ lb., 1 lb., and 5 lb., family or hospital size.

be no conflict with those of the physicians, invaluable aid will be rendered by them. In publicity work, in house visitations, in dietetic management, and in many other ways, the nurses should be used.

"3. Your committee would recommend that County Medical Societies actively participate in the management of tonsil-removing and other clinics.

"4. Your committee feels that it would be unwise to complete this report without cautioning the members of the different county medical societies that they must abandon their traditional position of isolation, and must take an active part in preventive medical and other health programs. We believe these activities will be conducted, preferably under the leadership of regularly licensed physicians; but when such leadership is not available without the cooperation of physicians and in spite of their antagonism. Such leadership entails planning, foresight, work, and cooperation to such an extent possibly not heretofore undertaken by the medical profession."

COLLECTING AGENCIES IN WEST VIRGINIA

The President's page in the September issue of the *West Virginia Medical Journal* contains the following remarks by President C. H. Maxwell, on collections:

"I suppose I have not used proper discernment in placing my accounts for collection. I find that a justice of the peace or a constable has better success than regular collecting agencies, and their commissions are less and success is greater. The law specifies their commissions, which are extremely reasonable. If suit is brought the expense is borne by the doctor, and no commission goes to the officer. Often when a careless one finds the grist in the mill ready to grind, he will become interested at once in the amount of toll to be taken.

"If one makes a regular custom of seeing that bills are paid promptly, there will be little complaint of poor collections except in grievous times like the present. Personal appeals have worked best in most cases. Yet some substantial private citizen with discretion is satisfactory.

"I sometimes envy the adeptness of some doctors in getting pay for what they do. Certain ones have everybody understand that if their services are to be had they must be paid for. This is fine from a purely financial business proposition.

"When I think of the immense amount of work done by some of us that has never been paid for, I feel envious of those who have met with financial success by making those that owe them come across with the goods, thus allowing them and their families to live in ease and comfort.

The Lockwood Colon Tube

N-8015

This perfectly moulded colon tube made by TIEMANN of an exclusive, secret rubber compound, and embodying the famous "Velvet Eye" feature, may now be purchased at the following prices, postpaid.

Nos. 34, 35, 36	\$2.00 ea.

CONFERENCES OF COUNTY SOCIETY OFFICERS IN IOWA

The December number of the *Journal* of the Iowa State Medical Society describes a new form of county society conferences in which two new features are introduced.

1. All the officers are included instead of the secretaries only.
2. The meetings are held in each of eleven councilor districts, instead of one for the whole State

The description reads:

"The 1931 conference of county society officers was held in a series of councilor district meetings instead of in Des Moines as in the past; and the remarkable attendance at these conferences as well as the resultant interest and activity, proved the plan highly successful. Secretary Parker proposed the district conferences as a means of promoting freer and more practical discussions of matters of common and local interest and the trustees approved the plan since it would greatly reduce the cost of the annual conference. Despite the fact that 245 county society officers, representing 87 county societies, attended the eleven councilor district conferences, the total cost to the Iowa State Medical Society was only \$207, as

compared with the \$1,558 cost of the largest previous conference, that of 1929, when 106 county society officers represented 73 counties.

"It is a noteworthy fact that of the 97 component county societies, 87 were represented at the various conferences, but still more significant was the active and general participation by all present in the discussions of State and county medical society activities. In several districts consideration was given to the formation of councilor district societies which are made practicable by the new division of the State into compact councilor districts.

"The programs of the conferences were practically the same, consisting of a presentation of State society activities expenditures and future programs, by various officers of the State society, followed by free discussion of these subjects and numerous local problems. In each case Dr Parker pointed out that in future conferences the ideal would be to devote the entire time to a consideration of local questions of medical organization and medical economics, which would be made the more feasible by the fact that such meetings are held in small compact groups."

STUDY CLUB IN IOWA

A physician's club is described in an editorial in the December *Journal* of the Iowa State Medical Society, as follows:

"With the advent of better means of communication through the use of the automobile over hard surfaced roads, there is little in the way of medical education and medical contacts which is denied the physician in the smaller communities. At one time, not so long ago, it was felt that the physician who did not locate in or very near to a large city became 'buried in the country,' and unless he was sufficiently progressive to make frequent pilgrimages to a Mecca of learning soon became obsolete in his practice. It is, indeed, pleasing to know that here in our State a group of physicians, quite removed from the larger medical centers, have, through coordinated cooperation developed a Medical Study Society, patterned after and apparently functioning as successfully as the medical clubs in teaching centers.

"Several months ago the progressive physicians of Fayette, Clayton, Delaware and Buchanan counties developed a plan of organization for a study club in which any member in good stand-

ing with his respective county society might obtain membership.

"Members of the club must participate in the preparation and discussion of all club programs, and that each member would assist any other member with advice or counsel upon request. Realizing that the life of such an organization depends upon maintaining a very active membership, their constitution provides that any member absenting himself more than three meetings during the year without good cause becomes automatically expelled, thus making room for the election of a new member.

"The club held its first meeting in May of this year, and has continued with punctuality to date. Current reports would indicate that the society is eminently successful and that great benefit is being derived by participants in the club's activities. The following lists the subjects and speakers at the meetings held since the new club came into existence:

"Arrhythmias, ear conditions, hyperthyroidism, pulmonary tuberculosis, x-ray in chest tuberculosis, obstetric anesthesia, and medical experience in Samoa."

MEDICAL ECONOMICS OF COLORADO, INC.

The December number of *Colorado Medicine* contains the proceedings of the Annual Meeting held on September 15-17, 1931, in Colorado Springs. The report of the Committee on Medical Economics discussed fee bills, accounting, collecting, professional advertising, hospital relations, the indigent, and public health units.

The Committee also gave much thought to a plan for incorporating the department of economics to the State Society, and presented the following outline of the organization and scope of the corporation.

"MEDICAL ECONOMICS OF COLORADO, INC.

"Organization

"(A) Executive

"1. Board of Directors

"a. Seven members; one each from Denver, El Paso, Pueblo, four from state other than above counties.

"b Method of election, by stockholders through House of delegates, from nominations by advisory council (Board of Trustees, Colorado State Medical Society.)

"2. Advisory Council (the Board of Trustees of Colorado State Medical Society shall constitute the advisory council of Medical Economics.)

"(B) Financial

"1. Authorized capital, \$1,000,000.00

"2. Authorized sales, 1,000 shares.

"3. Par \$100.00, quote \$150.00, \$100.00 into capital stock, \$50.00 into surplus.

"4. Initial paid-in capital, \$100,000.00.

"5. Initial paid-in surplus, \$50,000.00

"Object and duties of Board of Directors

"1. Transact all business of the State Society.

"2. Direct all policies pertaining to Hospital Relations.

"3. Direct in cooperation with the Advisory Council all policies pertaining to Public Relation with allied professions.

"a. Legislative Program.

"b. Public Health, Boards and other similar activities.

"c. Relations with Executive Staffs of Federal, State, County and Municipal hospitals.

"d. Relations with State Board Medical Examiners.

"e. Professional advertising.

FOOD FERRIN

THE BEST IRON FOR BLOOD BUILDING

PHYSIOLOGISTS long have known that the best iron for blood building is to be found in the green leaf of certain vegetables.

The trouble is in getting patients to eat or tolerate the excessive amounts of spinach, etc., which their anemic condition would demand.

However, it is possible to reinforce the organic iron in the regular diet by simply adding the scientifically prepared food-iron concentrate

FOOD-FERRIN

Extracted and concentrated from the chlorophyll of plants, Food-Ferrin has been described as a natural and physiologic source of iron.

Food-Ferrin is easy to take, easily assimilated — free from the well-known objections associated with the old-fashioned iron preparations.

Let us send you a physician's sample bottle.

PROGRAM OF ANNUAL MEETING IN TEXAS

The December number of the *Texas State Journal of Medicine* has the following editorial description of a new feature of the scientific program of the annual meeting to be held May 5-7, 1932, in Waco:

"The Council on Scientific Work has decided upon a radical change for the scientific work of the session. It is believed that the innovation will be received by our members as a splendid solution of our greatest problem. It is a sort of compromise between clinics or scientific assemblies, and the character of meetings heretofore held.

"First, the Council will request the House of Delegates to so arrange its meetings as to interfere as little as possible with the scientific work of the Association. A plan has been devised which it is believed will help to do this and to which the House of Delegates will likely accede. One of the criticisms usually advanced in connection with our annual sessions, is that delegates are not able to attend the meetings of the scientific sections, which is a two-edged sword.

"Second, the meetings of the sections have been so arranged as to leave clear the last two afternoons of the session.

"Third, the scientific sections will join in the General Meetings, on these two afternoons, the two programs being filled by the distinguished guests of the Association. In order to do this, it has been found necessary to crowd things a bit, beginning the meetings a little earlier and adjourning a little later, with a minimum time for discussions. It is believed that those who attend the annual sessions will warmly approve of the change."

It is requested that those who have papers to offer communicate with the proper section officers without delay. The program will be closed irrevocably January 15th. Other things being equal it is, of course, a matter of first come, first served.

THE CLINICAL SOCIETY OF THE NEW YORK POLYCLINIC MEDICAL SCHOOL and HOSPITAL

3. ESOPHAGEAL STENOSIS. (Motion Pictures and Lantern Slides). Chevalier L. Jackson, M.D. (by invitation)

Discussion opened by Harlow Brooks, M.D. General Discussion.

Collation

QUACKS IN IOWA

The editor of the *Journal of the Iowa State Medical Society* has written an editorial for the December issue in which he proves that Iowa is getting a reputation for getting rid of quacks. He writes:

"In the Omaha *World-Herald* of November 15th appears a full-page feature article headed, 'Rounding Up Medical Quacks in Iowa.' The article was prepared by one having access to the confidential files of the Law Enforcement Division of the Iowa Department of Health and accurately deals with the recent activities of this department. It is significant that these law enforcement activities should have been considered of sufficient interest and importance to constitute copy for a full-page story in the Nebraska daily. Our sister state evidently approves of our stand on law enforcement and our effort to rid Iowa of the public bloodsucker—the medical quack.

"An editorial in the Mason City *Gazette* entitled 'Iowa Lures Cancer Quacks,' states 'Iowa is "getting played for the sucker" by the cancer cure quacks. Whenever the authorities of another state clamp down on the faker, he invariably makes tracks for this state.' If this statement is true one can readily appreciate the attitude of the neighbor state in seeing news in the Iowa cleanup.

"With our State Department of Justice cooperating wholeheartedly with the Department of Health's investigators, positive action has been obtained of which we may justly be proud. The record is a good one and we have made and are making rapid strides toward giving the citizens of the state the protection in health matters that their lawmakers provided. Iowa is cleaning up and before long will be definitely off the sucker list of medical quacks."

Iowa seems to have been the happy hunting ground of the illegal practitioners; but within the last two years the State authorities have made great progress in eliminating the illegal practitioner, the quack and the faker.

ANESTHESIA—A ROUND TABLE DISCUSSION

On March 19, 1931, the Buffalo Surgical Society held a round table discussion on the subject of anesthesia, at which leading anesthetists of the city were invited to participate. The titles of the papers and their order of reading were as follows:

Ether and Nitrous-Oxid Anesthesia—Dr. J. H. Evans.

Avertin Anesthesia—Dr. E. H. Stumpf.

Spinal Anesthesia—Dr. J. B. Mulholland.

Infiltration Anesthesia—Dr. Marshall Clinton.

Carbon Dioxide, its Aid to Anesthesia—Dr. E. H. Stumpf.

Blood Pressure as a Safeguard in Anesthesia—Dr. C. J. Durshordwe.

"Don'ts" in Anesthesia—Dr. T. Craig Burns.

ETHER AND NITROUS-OXID-OXYGEN ANESTHESIA

By JOHN H. EVANS, M.D., BUFFALO, N. Y.

AS this is the opening paper in a symposium on the various kinds of anesthetic agents it seems advisable to consider briefly the field of anesthesia in its relation to the patient and the surgeon before dealing with the merits and demerits of ether and nitrous-oxid.

The anesthetist is an important member of the surgical team for the reason that the life of the patient is in his hands during the operation. A mistake in the dosage of the anesthetic or a failure to comprehend the condition of the patient may spell disaster. The ability to administer a given anesthetic so that the patient leaves the operating room alive is but a minor part of the anesthetist's duty, the major part being to know when the patient begins to show signs of approaching shock so that its establishment may be prevented and to judge intelligently as to the amount of surgery the patient is able to withstand. This he cannot do unless he has studied the patient beforehand and is aware of the patient's handicaps whether they be in defective kidneys, liver, heart, arteries, blood or lungs. His study should include a history of the case; for example, a loss of weight is a factor which detracts from the patient's endurance. An anesthetist has no right to anesthetize a poor-risk patient, especially for a serious operation without knowing as much about the patient as the surgeon does. Sometimes, unfortunately, this is very little.

The anesthetic and the anesthetist are closely associated with the operation. The anesthetist should be in position to observe the operation so

that he can anticipate the needs for relaxation. When he cannot see, it is necessary to carry the patient in a constantly deep anesthesia, thus unnecessarily inflicting upon the patient an excess of the anesthetic.

If the surgeon and anesthetist held more frequent conferences in selecting the anesthetic for the handicapped patient, the mortality rate would probably be reduced.

Anesthetics as a whole fall into two distinct groups, namely the revocable and the irrevocable. The revocable anesthetics are under direct control of the anesthetist, that is, the dosage may be varied at will and, if an overdose is accidentally given, it may be eliminated and the patient brought back to the zone of safety. This group is made up of the inhalation anesthetics, which include ether, nitrous-oxid, ethylene, chloroform and ethyl chloride.

The irrevocable group consists of those agents which, when once administered, cannot be recalled. If alarming symptoms develop, all that can be done is to combat them. It is impossible to reduce the amount of the agent in the circulating blood. In this group belong the various local anesthetics, cocaine, novocaine, neocaine, quinine urea hydrochloride, stovaine, sodium amytal, pernocton, avertin and colonic oil-ether. These agents are used to induce local, block spinal, intravenous and rectal anesthesia.

As the specialty of anesthesia has advanced and surgeons have become more alert to the importance of the anesthetic in the recovery of the

patient, there is a tendency to get away from using any one anesthetic routinely and to study the requirements of each case individually, especially the poor-risk patient. If any anesthetic is to be used routinely it should be selected from the revocable group. However, there are two agents in the irrevocable group namely, novocaine and quinine urea hydrochloride, whose toxicity when used for local anesthesia is so slight that their use routinely is justifiable.

The routine use of spinal, intravenous or rectal anesthesia is, in the writer's opinion, not justifiable for the reason that these methods of anesthesia are not yet sufficiently well developed as to make them entirely safe. They should be employed only in those cases where their special advantages more than out-weigh the danger incurred by their use.

Ether and nitrous-oxid-oxygen are the two most widely used anesthetic agents in this country and Canada. Each has distinct advantages and disadvantages. Used together they are capable of satisfying both the patient and the surgeon. Nitrous-oxid furnishes a pleasant induction for the patient and ether furnishes relaxation for the surgeon.

The advantages of nitrous-oxid-oxygen over ether are that it is pleasanter to inhale, is less irritating to the respiratory mucous membranes, disturbs metabolism less, does not interfere with the function of impaired kidneys as much and is more quickly eliminated.

The advantages of ether over nitrous-oxid-oxygen are that it is more reliable in producing muscular relaxation, is safer in the hands of the novice, does not require an expensive apparatus for its administration and is less costly.

Their comparative safety is dependent upon the qualifications of the one administering them. A report of deaths from anesthesia means very little

if the qualifications of the anesthetist are left out of the picture.

It is impossible to obtain a correct mortality rate for any anesthetic for the reason that the deaths are not published.

Dr. Keen has compiled records of 262,002 ether anesthetics with a death rate of one in 7,705.

Dr. Teter collected reports totaling 1,161,820 nitrous-oxid-oxygen administrations with but two deaths.

Dr. Buxton reports a compilation of 1,001,000 cases of nitrous-oxid-oxygen anesthetics with but one death.

Dr. Gwathmey estimates the rate in major surgery as being one in 20,000 with nitrous-oxid-oxygen.

The death rate from nitrous-oxid is, no doubt, much greater than these figures indicate.

In the hands of the qualified anesthetist the death rate from both ether and nitrous-oxid should be practically nil, the one having no advantage over the other as far as the safety of the patient during the operation is concerned.

The writer believes, however, from his experience of approximately 30,000 anesthetics, that the postoperative mortality and morbidity are less with nitrous-oxid-oxygen than with ether.

Although it has been repeatedly emphasized during the past twenty years that nitrous-oxid is a dangerous anesthetic in the hands of the untrained, yet surgeons have not become aware of this fact generally and many are willing to employ the novice who is equipped with a gas-oxygen apparatus.

The reason why nitrous-oxid-oxygen anesthesia is not safe except in the hands of those who have been properly trained is that the signs of deep anesthesia and approaching consciousness closely resemble each other and the novice is inclined to push the nitrous-oxid when he should be administering pure oxygen.

AVERTIN ANESTHESIA

By ELMER H. STUMPF, M.D., BUFFALO, N. Y.

MUCH interest has been aroused in Europe and this continent in the basal anesthetic avertin or tribromethylalcohol first produced by Willstaetter and Duisberg in Germany four years ago. Many reports of pharmacologic studies, clinical observations, together with articles by anesthetists, have appeared in medical journals, mainly European. In this country its use has been increasing rather rapidly in the past two years. Investigation of this drug, even though reports have been made of over 300,000 cases, is being continued in order to throw light on certain aspects of its action, indications and contraindications.

The early investigators were naturally handi-

capped by lack of knowledge of its effects, and in the attempts to produce complete anesthesia with this drug, a number of fatalities resulted. It was not until the dosage was reduced to a point where its action became basal, requiring the addition of either general or regional anesthesia to produce the complete anesthetic effect, that its use became widespread, first in England, then in the United States and Canada. Anesthetists generally, we have found, use a moderate dosage of 70 to 90 milligrams of avertin fluid per kilogram of body weight for the average adult patient, the variation depending upon physique, age, and general physical condition; but the Germans are now advocating from 85 to 95 milligrams.

This avertin fluid is a solution of avertin in amylene hydrate, 1 cc containing 1 gm of the drug. It is readily soluble in water. The solution of avertin fluid in water (distilled) must be freshly prepared for each case, and at a moderate temperature of 100° to 104° F. It may be a few degrees below this limit, but extreme care must be exercised not to allow the temperature of the water at the time of mixing to rise higher than 104° F. Above this temperature hydrobromic acid is split off with formation of dibrom-acetaldehyde. This will cause marked irritation and even necrosis of the intestinal mucous membrane. A few drops of Congo red are used to test the solution at each preparation. A pink color signifies the solution is stable, while a violet tinge indicates that deterioration has taken place, and it must not be used. The dosage is estimated from tables depicting the exact amounts of the ingredients for each 2 kilograms of body weight up to 100 kilograms.

The patient is prepared in the usual way, with sedation the night before operation, when the cleansing enema is given. The rectal irrigation should not be given within two hours before injection of the avertin solution, as the fluid remaining in the bowel may delay absorption. We advise against the use of morphine preliminary to operation, since it increases the depressing effect of the avertin on the respiration. The injection is made rectally with the patient on the left side. We prefer to have him (or her) on the surgery cart. The room is then darkened. As avertin is rapidly absorbed from the rectum, consciousness is lost quickly and quietly. Usually within five minutes the patient's eyes close and he will respond languidly to questions. In fifteen minutes more he is usually ready for the operation.

There is usually a decline of 10 to 30 mm in the systolic blood pressure, which seems to be temporary and may be effectively controlled by ephedrine. The breathing is quiet and regular, somewhat depressed, and the color is usually normal. It is of supreme importance that the air passages remain clear, so that respiration may be in no way impeded. It may be necessary to add some carbon dioxide in the mixture of gases being used for anesthesia. Experiments have been made on dogs showing the beneficent effect of a free respiration on the blood pressure. The amount of nitrous oxide or ethylene used may be reduced markedly, increasing the oxygen to as much as 50% or more. The narcotic effect of the avertin usually begins to disappear in 45 minutes although the decrease in the density of narcosis is gradual. We advise against its use in combination with spinal anesthesia because of the depression of circulation and respiration.

The patient will usually fall asleep after regaining consciousness momentarily and may sleep from two to twenty-four hours or more. The

amnesia is a good feature, patients having only a hazy recollection of events for the first several days after the operation. Liquids are tolerated soon after return to bed and nausea is infrequent. The patient should be constantly watched while in this somnolent state, so that the air passages remain clear. Frequent shifting of position is advocated, of course, as soon as possible after the effect of the narcosis has disappeared, as with other anesthetic agents.

Data recently submitted by Widenhorn of Freiburg throw significant light on the effect of avertin on the blood. Tests were made before and after operation, avertin being used alone as the anesthetic agent, and in smaller doses with ether, nitrous oxide, and ethylene as supplementary anesthesia. It was shown that avertin alone lessened the carbon dioxide combining power of the blood markedly, producing a prolonged period of acidosis lasting twenty four hours or more, also showing a large increase in blood sugar. When combined with ether the effect was almost the same, only slightly less in degree. Avertin combined with nitrous oxide oxygen or ethylene oxygen anesthesia produced little change in the carbon dioxide combining power of the blood or the blood sugar. From these studies it would appear that avertin used as basal anesthesia with either nitrous oxide or ethylene offers the best results.

Because of its irritating qualities avertin is contraindicated when lesions of the rectum are present. Other contraindications are an impaired circulatory system, severe organic disease of the liver, serious bilateral disease of the kidneys, acidosis, debility, grave cachexia, excessive obesity and dehydration. While children are more tolerant to avertin than adults and no allowance need be made for youth in determining the dose, it should not be used in the aged. It is much more efficient in small dosage, the effect depending more on the rapidity of its action than the amount used. If the blood pressure is low, 50 milligrams of ephedrine in the enema will stabilize it nicely.

While avertin has been found to be ideal in brain and cord surgery, producing fewer post-operative complications, the writer has still to be convinced that its advantages outweigh its disadvantages when used for general surgery. Considering the possibility of irremediable damage through unsuspected rectal liver or kidney pathology, the depression of respiration and circulation, the difficulty of gauging the depth of anesthesia and maintaining a proper level with supplementary nitrous oxide or ethylene and the tendency to hypoventilation of the lungs in the postoperative sleep because of possible inattention to obstruction of the air passages it seems that the barbiturates combined with nitrous oxide or ethylene or gas ether sequence anesthesia produce very nearly the same hypnotic effect, and more safely.

SPINAL ANESTHESIA

By JOHN B. MULHOLLAND, M.D., BUFFALO, N. Y.

IN recent medical literature there has appeared a tremendous amount of discussion on spinal anesthesia. Most of the surgical and anesthetic meetings have devoted a section to this topic. In this manner a vast wealth of experience and information has furthered the advancement of this form of anesthesia. According to some, spinal anesthesia should be considered an analgesia, because all forms of sensation are not abolished by the intra-spinal block, which consists of an injection of anesthetic solution into the subarachnoid space, bathing the roots of the cord within the dural cavity. It will be observed that loss of sensibility to pain will constitute a complete and successful operative state; yet the patient may tell you of tactile sense, pressure, traction and sense of heat and cold.

It is not the intent of the writer to cover the ponderous work that has been done on spinal anesthesia, but to bring briefly to your mind that Corning was the first to experiment with it in 1885—to 1888. Dr. Bier of Germany really got the credit for its practical application to surgery. Since that time spinal anesthesia has run the gamut of pit-falls, starting with cocaine, tropocain, stovain and novocain as the anesthetic agents. Cocaine probably contributed largely by its toxic action, to the disrepute that befell this form of anesthesia, for a considerable period. A few men, firm in their convictions as to the merits of spinal anesthesia, withstood the barrage of criticisms for a number of years. One, I might add, was Dr. Babcock, who kept improving his methods and solution, so that he has lived to see the barrier of prejudice melt away.

The cerebrospinal fluid is continually being secreted by secretory or epithelial cells of choroid plexus and ependyma membrane. The volume of fluid ranges from 50-150; average 100 cc. in the subarachnoid space, the ventricles of the brain and the central canal of the spinal cord, the specific gravity of clear watery fluid being 1.004-1.007. The movement of fluid is drained from above down through the arachnoid, sheath of the spinal and cranial nerve roots and perivascular lymphatic sheaths. Permeability is from within outward and endosmosis does not occur. The pressure of spinal fluid is about 100 mm. water or 10 mercury.

The principal agents in use today are novocain, stovain and nupercain, each of these agents having been modified or enhanced by additional medication to bring about solution, which in themselves offer certain advantages in technic.

Novocain may be used alone in purified crystals known as neocain. This is dissolved in the patient's own spinal fluid. Dosage is usually about 1 centigram to 15 pounds body weight. In cer-

tain clinics this method is highly admired. Often no premedication is used and no ephedrine nor adrenalin employed. Diversity of opinions always brings forth newer ideas. Barker used glucose to make a heavier-than-spinal fluid mixture with novocain solution. The solution with glucose was designated as non-diffusible, while solutions of novocain or stovain with alcohol added to make lighter solutions, were known as diffusible. Lactic acid has been added to solutions to overcome chemical action of sodium chloride or other alkalies, which deteriorate the action of novocain.

Stovain and strychnine have been used extensively in the past. Stovain, lactic acid, absolute alcohol and aqua distilled, is one formula used by Dr. Babcock. He says after using many preparations he prefers stovain as a basic agent. Nupercain is a quinine derivative used in 1-200 solution, 2 cc. for spinal injection in the usual manner. Four to six hours anesthesia is claimed. Some surgeons combine nupercain $\frac{1}{2}$ and neocain crystals $\frac{1}{2}$ for a long anesthesia. Spinocain, developed by Dr. George Pitkin, has a novocain base with strychnine and gliadin (which is the mucilaginous portion of wheat starch) and delays dissemination of anesthetic solution. Alcohol is added to make it lighter than spinal fluid. Strychnine is also introduced to off-set depression and the toxic action of novocain.

Spinocain by now has reached a wide acquaintance of users. Many have been greatly pleased with the action of this solution because it offers:

1. Controllability.
2. Sure and longer anesthesia.
3. Less shock.
4. Less acidosis.
5. Less dehydration.
6. Less suppression.
7. Less headache.

Sphincter paralysis is seldom seen with this solution. It must be thoroughly understood that in using any method of spinal anesthesia, the advocate's instruction should be rigidly adhered to in order to attain the best results and to avoid more hazards.

Stovain is slightly more toxic than novocain. In experimentation on animals with 2 or more repeated injections of stovain, there later appeared degeneration of some of the anterio-lateral tracks of the cord itself, but no action on roots. Repeated injections of novocain did not cause any degeneration of cord or roots. Likewise the examination of spinal fluid following stovain injection in humans sometimes shows an increase of the cell

count often to 50, while following the use of novocain, no increase of cell count appeared. Barbitals has shown a decided antidote action for large doses of novocain and for this reason, barbitals has been advised in premedication.

The use of alcohol in the solution acts not only as a preservative, keeping the solution sterile, but tends, I believe, to enhance the anesthesia, also aiding in diffusibility and making the solution lighter for control feature. It is used in 7-10% amounts. Few cases of abducens paralysis have occurred since its adoption.

It is needless to say that this type of anesthesia should not be used as a routine. Some consideration must be allowed the patient. Willingness of the patient should come first if no operation is expected. Cases in which you know spinal anesthesia is best, the patient must be consulted and offered truthful explanations for its advantages. The patient will usually accede, if he has confidence in his doctor. Pushing spinal anesthesia on patients who are ward cases or compensation cases, without their knowledge, will soon bring condemnation on this invaluable form of anesthesia. Some people detest ether and some prefer to be conscious, but the success of many operations depends on the relaxation which can be obtained best with this type of anesthesia. In short, any patient that has the contra-indication for general anesthesia, usually becomes a suitable subject for spinal anesthesia (anatomically limited, or from the diaphragm down).

<i>Favorable</i>	<i>Unfavorable</i>
Diabetes	Mental instability
Toxemia	Severe shock
Severe infections	Advanced cardiac lesions
Acute T B.	Pleural effusion
Chronic T B	New growth in chest
Chronic nephritis	Advanced arterio sclerosis
Uremia	Hypotension below 80 mm systolic pressure
Cholemia	
Eclampsia	
Mitral stenosis	
Hemiplegia	
Alcoholism	
Asthma	
Drug addicts	

These various conditions are not particularly absolute, but this is where the experience of the surgeon and anesthetist counts, in being able to eliminate the risks. As one prominent surgeon says "You get a hunch."

Do not expect the debilitated patient with one foot on a banana peel and the other foot in the grave to weather the ordeal. Robust youth with firm tissue, stout heart and courage do better under this form of anesthesia.

Premedication. Give Barbitals in the evening and morning preceding operation, 5 gr each to overcome toxic action of novocain, and morphine

in fractional doses, $\frac{1}{4}$ gr, 75 minutes before operation. Also scopolamine about 1/200 to act on the intrinsic nerve fiber of the vagus. These drugs used judiciously offer a great deal of solace and tranquilize the patient. Many patients sleep along during the anesthesia.

Technique. Personal supervision in sterilization of needles and solutions should be encouraged by the anesthetist. The procedure of administration should be conducted in the fashion of a minor operation—under aseptic conditions, skin to be prepared from nital cleft to costal angle with iodine and alcohol, and patient draped. Select the interspace and deposit local infiltration of skin and supraspinous ligament with novocain and ephedrine. Test needle for breakability, go in a straight line between interspinous ligament to the dura, a snap will be transmitted to the operator when going through at this point. Use small calibre needles and do not allow too much of the spinal fluid to escape, as this prevents headache later. Use Luer-lock needles that do not permit air to enter or fluid to escape and inject solution very slowly. On the tap, if spinal fluid shows pus, do not inject but treat case for meningitis. Yellow spinal fluid or Zanthochroma is indicative of stasis, very often brain tumor, in which case do not inject solution as the results are usually disastrous. If fluid is bloody, wait for fluid to clear before using syringe. Known cases of cerebro spinal syphilis should not be anesthetized as their symptoms are often aggravated.

After the patient has been injected, he may be put in slight Trendelenburg position. The eyes may or may not be covered, to suit the wishes of the patient.

The reactions presented by the patient are usually of transient nature and require intelligent care rather than actual treatment. The symptoms are variable and may be expected to appear in this order:

- 1 Slight flush of the face from ephedrine
- 2 Slight drop in blood pressure
- 3 Slight nausea
- 4 Consciousness of traction
- 5 Occasional complaint of pain left shoulder (phrenic neuralgia)
- 6 Slight pallor
- 7 Restlessness

Many of these are dependent on fall in blood pressure, in which case 5 mm of adrenalin may be injected in the deltoid, massaging the area and repeating if necessary.

Respiratory embarrassment is an alarming symptom, though frequency and gravity are proportional to the amount of novocain used and the method of its control, also on the experience of the anesthetist. Anesthesia is too high, when patient cannot talk above a whisper, or there appear

a mild degree of cynosis and the blood pressure may register zero over nothing. Then increase the Trendelenburg position and use oxygen. During the operation words of cheer and confidence should be offered to encourage the patient; of course, no disquieting news should be given to alarm the patient. The surgeon can contribute greatly to the success of spinal anesthesia by operating with speed that is consistent with thoroughness. Gentle handling of viscera in the manner practiced under local anesthesia can be expected to give the patient better convalescence from increased amount of abdominal distension as a post-operative factor. In Cesarean section, use no premedication because it causes difficulty in starting respiration in the new-born. Uterus,

ureters and intestines contract under spinal anesthesia and involution of uterine muscles occurs uninterrupted. Spinal anesthesia is contra-indicated in ruptured ulcers of the stomach or bowel.

The percentage of failure at anesthesia runs from 1% to 30%, depending on the operator. A review of deaths from spinal anesthesia shows about 1-1,000.

An absolute and uncompromising inspection of spinal anesthesia carefully conducted, will convince you that it is best for greatest relaxation, less post-operative sequelae and time saving. A short circuit to recovery. It has a distinct place in surgery. Its scope has widened and will continue to widen as indications and contra-indications are more clearly understood.

INFILTRATION ANESTHESIA

By MARSHALL CLINTON, M.D., BUFFALO, N. Y.

Infiltration anesthesia was introduced many years ago for the performance of various kinds of surgical procedures. While never developing into a method of choice in general work, it has found a place in the armamentarium of the surgeon.

During the development of infiltration anesthesia, it was found that there are two main factors on which the efficiency of this method depends—first, the concentration of the drug used; second, the degree of infiltration of tissue by the solution. The stronger solutions of any of the cocaine derivatives were more efficient in infiltration anesthesia as the various sensory nerve filaments were more quickly brought into contact with the stronger solutions.

It was found after trial, however, that very weak solutions could be used and their efficiency depended upon. Their success depends first, on the complete infiltration of all the tissues in the field of operation, and second, waiting a proper length of time until these weaker solutions could affect the filaments in the operative area. Today, we have derivatives of cocaine which are almost non-toxic. Years ago, we used novocaine in 1/2, 1/5, 1/10 of 1% solution. The method of anesthesia, not the drug is important.

An experiment which we reported many

years ago in the State Journal succeeded in producing complete anesthesia in a double herniotomy by the use of sterile water, but to produce anesthesia, we had to produce the maximum amount of edema of every structure to obtain an anesthetic effect. When inflammatory lesions reach the stage of edema, pain automatically begins to decrease which is the same effect as that produced by infiltration anesthesia.

In observing local anesthesia operations, we think that the students are not taught in the Medical School as they are in the Dental School, that after the injection of a local anesthesia, especially when a weak solution is used, a period of five or more minutes should elapse before any surgical procedure is attempted.

We still believe that in an ordinary operation, when the more painful structures such as skin and peritoneum are anesthetized before incision and the peritoneum blocked after the operation by 1/4 of 1% solution of quinine urea hydrochloride, we have materially diminished the volume of pain impulses that patients receive. Their postoperative convalescence is generally more comfortable than when quinine urea has not been used.

The big point of local anesthesia is that tissues have to be well infiltrated and hands and instruments must be used with gentleness.

CARBON DIOXIDE—ITS AID TO ANESTHESIA

By ELMER H. STUMPF, M.D., BUFFALO, N. Y.

THAT carbon dioxide is an essential factor in the smoothly and safely conducted inhalation anesthesia has long been recognized by anesthetists. This has been particularly so since nitrous oxide came into general use as an anesthetic agent with the manufacture of various types of apparatus for its delivery. The principle of re-breathing is used in these machines, whereby on the average 300 to 400 cc. of the patient's exhaled breath, depending on the tidal volume, are re-inhaled, thus using only 100 to 200 cc. of fresh gases with each respiration.

This practice has been found to result in

1 A saving of gases

2 A stabilization of respiration through the stimulating effect of the carbon dioxide on the respiratory center

3 The replacing of the carbon dioxide eliminated from the blood stream through the increased tidal respiration of anesthesia, thus preventing acapnia or lack of carbon dioxide, the tendency being rather to hypercapnia, thus conserving the alkali reserve of the blood, which depends on the carbon dioxide concentration, and guarding against post-anesthetic acidosis

4 The reduction of post-anesthetic nausea to a minimum because of this conservation of the acid base balance

5 The reduction of the amount of the anesthetic agent needed, especially when ether is used a much lower concentration sufficing

In recent years, following extensive experimentation by the physiologists Henderson and Haggard, and various anesthetists, notably Watters, Sword, Chipman and others, the manufacturers have equipped the machines for the use of four gases, nitrous oxide, ethylene, carbon dioxide, and oxygen. Many anesthetists are now using carbon dioxide from the tank, either in the form of a mixture with oxygen, called "carbogen," or pure, in conjunction with the other gases at various stages of the anesthesia. It has been found to materially assist in the smooth induction of a gas ether sequence in concentrations as high as 30 per cent. The blood pressure rises, particularly marked in those cases where the blood pressure has fallen below normal, the rise being due, according to Hanau, to an increase in the supranal output. It stimulates the vasomotor centers dilates the heart but increases diastolic and systolic volume.

We have found it of great value at the conclusion of gas oxygen ether anesthetics to "de-etherize" the patient, and have so used it for the

past several years. The administration of a 5 to 10 per cent mixture of carbon dioxide and oxygen for several minutes at the conclusion of the operation produces a thorough hyperventilation of the lungs and the ether is rapidly eliminated. Reflexes return promptly and, by the time the patient returns to the bed, recovery from the anesthesia is very nearly complete.

In addition to this "de-etherization," the hyperventilation of the lungs overcomes the condition which is the prelude to post-anesthetic atelectasis. In a prolonged operation, the depression in the sensitivity of the respiratory center to stimulus, caused by the preliminary medication of morphine and the anesthesia, proves too much for the normal 5.5 per cent pressure of carbon dioxide in the blood to overcome. The diminished respiration which you may notice when the mask is removed causes a clogging and blocking of the lung air ways or bronchioli by plugs of mucus which may easily lead to an atelectasis and the conditions characteristic of an undrained infection within 24 to 48 hours. This is often aided by the patient's deliberate lessening of tidal respiration after consciousness has returned because of the pain from a high abdominal incision. The center responds nicely to 5, 7, 10 to 15 per cent carbon dioxide according to the degree of depression, the 5 or 7 per cent mixture being sufficient in the average case.

When post anesthetic atelectasis has developed we have administered carbon dioxide and oxygen with gratifying success. The marked and rapid rise in temperature, the trichypnea, the tachycardia and general distress are usually relieved promptly. There is no better way to abort the incipient pneumonia.

In conclusion, we are using carbon dioxide and oxygen routinely at the end of the operation to hyperventilate and "de-etherize" the patient when ether has been used. We have the tank close at hand during a spinal anesthesia in case of severe respiratory depression, although we have been fortunate thus far in not needing it. We have observed that it has overcome respiratory failure during anesthesia when oxygen alone, delivered under pressure, had failed. We administer it at the first sign of atelectasis or embarrassed respiration from other causes after operation. We have found it valuable in post anesthetic hiccup. While expert anesthetists use mixtures up to 30 per cent carbon dioxide, we would caution against its use by the inexperienced in mixtures over 10 per cent which is normally the border line between stimulation and depression.

BLOOD PRESSURE AS A SAFEGUARD IN ANESTHESIA

By C. J. DURSHORDWE, M.D., BUFFALO, N. Y.

THE purpose of this paper is not to reveal anything new, but to review some of the methods which we have at our disposal, that, when applied, aid in safeguarding the life of the patient. And safeguarding the life of the patient, when the final word is said, is the primary responsibility of both anesthetist and surgeon.

These methods require a certain amount of extra work that is easy to omit for it, seemingly, has little if any bearing on the actual giving of the anesthetic. However, the routine pre-operative examination, besides giving us an opportunity to become acquainted with the patient and win his confidence, affords us certain definite data that enable us to select the type of anesthetic most suitable in carrying the patient smoothly and safely; and also enable us to make a prognosis of the patient's chances of withstanding both the anesthetic and the shock of the operation.

In entering into a discussion of the value of recording blood pressure readings before and during anesthesia, I feel that the technique is familiar to all and a description of it may, therefore, be omitted. However, it might be well to reiterate the general principles governing the blood pressure picture and to attempt to show the importance of the correlation of these principles to the surgeon and the anesthetist in safeguarding the patient.

Primarily, blood pressure depends on the force of the contractions of the heart, the elasticity of the vessel to accommodate the additional blood from the contracting heart, the amount and viscosity of the blood and the vasomotor control.

The systolic pressure is the pressure of the heart at the height of contraction; the diastolic pressure is the pressure of the resting heart; the pulse pressure is the difference between the two; or as Adams states—the "working pressure" of the heart.

The diastolic pressure is more constant and, therefore, a better guide than was formerly supposed. Langford, in a recent article in "American Medicine," made several statements with reference to diastolic pressure which are important enough to bear repeating. He says: "The diastolic pressure is less variable and if persistently up to 100 or more, kidney complication is becoming important. If ranging 120-160 (diastolic) and not reducible by corrective measures, the kidney disease is grave and the phthalein efficiency will be found below 40%. Essential hypertension is a misnomer, or rather, it is cardiorenal disease in its incipency." These statements are borne out by a study of insurance risks from the companies' points of view. They place a diastolic pressure above 94 as in the "possible danger zone." Evans, even more conservatively, places the normal between 74 and 90.

The systolic pressure varies greatly as it is easily influenced by physiological factors: fear, excitement, anger or nervous strain and conversely, does not hold the importance once attributed to it. Grover states that "while the systolic pressure taken alone may give some idea of the vascular tension, it is of little value in interpretation." One of New York's larger insurance companies places 140 mm. as a normal maximum for the systolic pressure of healthy men and women. "It is quite within the limits of safety," says Evans, "to consider the normal systolic pressure as 100-140 mm. in adults regardless of age, sex, height or weight."

Pulse pressure, which is credited by Adams with being the most important single feature of the blood pressure picture that aids in the prognosis of the ultimate outcome of the operation, is placed normally between 39-50 mm.

It would be very desirable, were it possible, to make a set of rules governing the limits between which the systolic, diastolic and pulse pressures were safe or dangerous as the case might be. Unfortunately, this cannot be done. Each case must be studied and treated as a separate problem. Granting that certain factors are more important than others, it is the consideration of the blood pressure picture as a whole that affords us the best data for interpretation.

Barach has worked out a rule of energy index which is based on the amount of energy expended by the cardiovascular system per minute that is very simple to apply and is a useful working guide to the ultimate outcome. Normal range of safety is placed between 13,000 and 20,000 and is computed by multiplying the systolic and diastolic pressures by the pulse rate and adding their results.

Moots evolved an index of operability that utilizes the ratio between the pulse pressure and diastolic pressure and is expressed in percentage. He states that cases where the "pressure ratio lies between 25% and 75% are probably operable."

Froes' nerve shock index, while not depending entirely on the blood pressure readings, is deserving of consideration as a prognostic sign. The test is made as follows: Multiply the patient's systolic pressure by 100 and divide the product by the hemoglobin per cent times the numeral indicating the hundred-thousandths of red blood cells. To illustrate: A patient with a systolic of 170, having a blood count of 3,500,000 and a hemoglobin of 65 would have an equation thus:

$$\frac{170 \times 100}{35 \times 65} = \frac{17000}{22.75} = 744$$

The limit of safety according to Froes' law is 7. Any case with a resultant answer above 7 is likely to suffer shock. Not having used this rule sufficiently to express any personal opinion that would be worthy of consideration, I must resort to the opinions of some of the men who have

Dr E E Lashbrook of the University Hospital of Iowa City states "Froes' Nerve Shock Index is apt to give a more illuminating prognosis of the risk that the patient runs than even Moots' Index based on the deviations from normal of the pulse pressure ratio per cent."

Dr E Klaus of Cleveland, after pointing out the difficulties in obtaining accurate hemoglobin percentages that are so important in the computation, summarizes by stating "I feel that it has possibilities for routine use in connection with other tests for the evaluation of risk and should not be neglected."

Dr Harry Lakin of Harrisburg believes the Froes' nerve shock index is the "most reliable test of operative risk that we have" and in his series of cases stated that every abdominal operation case in which the index was over 7, evidenced shock.

The spectre facing the surgeon and the anesthetist during an operation is the ever present possibility of the patient going into a state of shock. This may be induced by surgical trauma in exploring and roughly handling the tissues, by using cold packs or too many packs in the abdomen, or by the loss of blood. Nor can we lose sight of the fact that the depressing effect of the anesthetic, per se, may induce this condition. After the initial rise in the blood pressure due to the stimulating effect of the anesthetic and occurring usually during the first fifteen minutes we have its depressing effect, depending on the kind of anesthetic used, the duration and depth of the narcosis under which the patient is carried.

The outstanding single feature of surgical shock is the constant drop in blood pressure. This

feature is always present and occurs for some time before there are any other signs of the impending condition and early enough to enable the anesthetist to inaugurate measures to counteract its effect and aid in saving the life of the patient. The fall in blood pressure may precede all other evidences of shock by from five to twenty minutes.

With a fall in the blood pressure we usually look for an increase in the pulse rate to compensate for the lowered pressure. However, with a lowering of the blood pressure there is a lowering of the function of all the organs, including the heart and a depression of the central nervous system, so that the rise in pulse rate and other manifestations of shock may not come under our observation for some time after the fall of blood pressure. Thus much valuable time has been lost in aiding the patient to overcome the handicap under which his system is working.

A point that cannot be over-emphasized is the cooperation necessary between the surgeon and the anesthetist. Apathy on the part of the surgeon, or failure to heed the warnings of the early signs of shock as evidenced by the blood pressure picture, may result disastrously for the patient if the necessary means of combating the condition are not employed. Nor can the cooperation of the surgeon be overlooked in making a prognosis of a case. A slow operator or one who will not act during the operation or who fails in his post-operative care to maintain a blood pressure bridge, adds considerably to the operative risk.

In closing may I emphasize that blood pressure records may assist greatly in the evaluation of the risk which the patient faces, as well as furnish useful and important information of the condition of the patient during the operation. In my opinion, it is the composite picture of the blood pressure findings that must be considered and interpreted. These rules, to which I have referred, are not infallible but their application will assist in safeguarding the life of the patient.

"DON'TS" IN ANESTHESIA

By T C BURNS MD, BUFFALO, N Y

THE first and most important Don't is not to lose sight of the responsibility of carrying a patient through a surgical operation, taking away his sensibility without a general motor paralysis and restoring him to normal. The anesthetist must work with the surgeon to accomplish the best surgical results with the least amount of physical disturbance. There must be team work. The anesthetist should anticipate the moves of the

surgeon so that there will be proper relaxation at the right time. For example, in closing the peritoneum, when nitrous oxide is being administered, secondary saturation produces relaxation, causing an easy approximation of the peritoneum.

Next, don't forget that there is not only a choice of anesthetics but also of methods. But in choosing, the patient's safety is the most important consideration. It was not so long ago that

our stand-bys were ether and chloroform, but today, along with them, we have spinal, avertin, locals, nitrous-oxide-oxygen and ethylene. There is no need of going into a discussion of these agents as they have already been discussed by other essayists here tonight. It sometimes seems to me that we all get into a rut and are liable to adapt our cases to the anesthetic, instead of the anesthetic to the case. Each anesthetic has certain advantages and disadvantages and I believe the choice should be made after carefully weighing the facts in each individual case, especially for the handicapped patient.

How can we best conserve the patient's vitality? It is sometimes easy to diagnose, for instance, a cardiac complication but quite different to estimate accurately myocardial exhaustion and give dependable judgment upon the operability of the patient. However, besides the history, we have to aid us in a preoperative estimation of the surgical risk, the blood pressure, which is most valuable as it may indicate nephritis, myocarditis, traumatic shock and high blood pressure. The index has the pulse pressure as the numerator and the diastolic as the denominator. In health, a fraction of $\frac{1}{2}$ or 40/80 is normal. In myocarditis and traumatic shock it is lowered, and increased in nephritis and aortic regurgitation. The energy index, obtained by multiplying the sum of the systolic and diastolic pressures by the pulse rate per minute and eliminating the last three figures in the result, gives a normal of 16, the normal range being 12 to 18. This represents the energy expended by the circulatory system in one minute. We also have the breath-holding test which is important. If the patient is unable to hold his breath at the end of normal expiration for 25 seconds it indicates lack of cardiac compensation.

The anesthetist should not neglect, some time previous to the operation, to make an examination of the patient, especially the heart, lungs and mouth, and to read the history on the chart before giving an anesthetic, not only for the patient's safety but for his own benefit and protection. In the physical examination of the heart it is safe to assume that the larger the heart, the poorer the risk, as it is evidence of myocardial damage. Also those hearts which haven't clear cut sounds or have re-duplication of the first heart sound indicate danger of failure in a hypertrophied heart. Confidence will be instilled in the patient by a

careful examination as there is not one-third the fear of an operation as there is of the anesthetic. The anesthetist who makes it a rule to perform a careful examination of the patient enhances his position in the surgical team and helps to make surgery safer. It is my opinion that there is only one place to give an anesthetic, except, of course, in an emergency, and that is in the hospital where all clothing can be removed and the proper care and precautions taken.

The anesthetist's responsibility during the operation is to acquaint the surgeon with the condition of the patient, helping him decide as to what the patient can stand and upon the first signs of approaching shock to order stimulation, not waiting until a vicious cycle is established. The most dependable stimulant is Digitalis which increases cardiac tonis enabling the heart to expel the same amount of blood as before with smaller heart volume. It causes a general constriction of the vessels with a consequent decrease of total capacity of the vascular system. The intravenous preparations as digitan solution and digifolin are used. Other drugs such as caffeine sodium benzoate, adrenalin and pituitrin, which have more rapid but less lasting action, may be given to carry on until salines, glucose and transfusions are started. It is advisable to give glucose solution before severe operations where the liver deficiency is suspected, as in jaundice. Also where the metabolic rate is high as in Graves' Disease, in under-nourished cases, after severe operations where loss of blood has been great, and in those postoperative acidoses and dehydrated conditions in which the patients need dextrose and water. They are starved and thirsty and have a constant hyperglycemia.

In giving anesthesia, remember that the principal signs to watch are the pupillary reflexes, pulse, blood pressure, breathing, whether free or obstructed, muscular relaxation and color. Do not look for cyanosis in cases of traumatic shock and anemia which have that ashen gray color. Great care should be exercised when giving nitrous oxide to these cases as this gas is taken up more readily than oxygen and a condition of anoxemia results which cannot be estimated by cyanosis on account of the low hemoglobin content.

In closing, may we repeat, don't forget the importance of the anesthetist and his responsibility in the administration of the anesthesia.

RECORDED AND RESIDENT DEATH RATES IN NEW YORK STATE

By J. V. DE PORTE, Ph.D., ALBANY, N. Y.

Director, Division of Vital Statistics, New York State Department of Health.

No. II—TUBERCULOSIS, ALL FORMS: 1926-1930

THE recorded death rates from tuberculosis in 1930 in the sixty-two counties of the State ranged from a minimum of 7.8 per 100,000 population, in Schuyler to a maximum of 446.3 in Franklin—the rate for the entire State being 70.9. A variation of such magnitude cannot be explained altogether by the greater or lesser salubrity of climate or differences in the make-up of the population according to nativity, sex, age, occupation; it is influenced by some extraneous factor which is evidently the matter of residence. Franklin County, with the highest recorded death rate, has a number of nationally and internationally celebrated institutions for the treatment of tuberculosis, most of whose patients are non-residents of the county. This is also the reason for the next highest death rate—371.2 in Sullivan County, and the rate of 325.8 in Essex.

The table below shows the death rates from tuberculosis per 100,000 population, recorded and corrected for residence, in New York City and in the urban and rural Upstate territories in 1926-1930:

The effect of the allocation of deaths according to residence is most significant. Considering the figures for one year, 1930, we note that the New York City rate is increased by 10 per cent while the death rate of the rest of State is decreased by 13 per cent. The most interesting fact is the reversal in the relative position of the rates of the urban and the rural Upstate sections. The recorded rate of rural New York is 53 per cent above the urban (exclusive of New York City); when a correction is made for residence it is

of places over 25,000 population there were but four exceptions:

	<i>Recorded</i>	<i>Resident</i>
Buffalo	75.6	71.1
Kingston	124.6	92.6
Newburgh	83.0	54.3
Rome	67.6	47.3

Rural Area of Counties. The resident death rates are lower than the recorded rates in the rural areas of the majority of the counties. While thirteen counties had recorded rates in excess of 100, only one had a resident rate of such magnitude—Hamilton (102.2), this rate being based on only 4 deaths.

The following table shows the rural recorded and resident tuberculosis rates of the thirteen counties mentioned above:

	<i>Recorded</i>	<i>Resident</i>
Dutchess	396.8	67.6
Essex	111.7	63.9
Franklin	333.8	69.9
Greene	131.0	97.0
Herkimer	111.6	58.0
Monroe	102.4	37.8
Montgomery	160.0	85.0
Oneida	107.8	75.7
Onondaga	110.3	49.9
Rensselaer	164.0	67.5
Schenectady	190.3	63.4
Sullivan	199.1	64.0
Westchester	123.7	37.5

YEAR	NEW YORK CITY		REST OF STATE		URBAN		RURAL	
	Recorded	Resident	Recorded	Resident	Recorded	Resident	Recorded	Resident
1926.....	85.4	94.2	85.2	74.6	70.6	83.3	88.4	60.0
1927.....	78.1	85.9	78.2	68.8	64.3	75.2	81.7	57.4
1928.....	79.4	88.0	77.4	67.0	63.6	73.9	82.1	56.2
1929.....	75.5	83.3	74.0	64.5	58.8	71.1	80.6	54.1
1930.....	73.1	80.3	68.3	59.5	51.5	63.3	78.6	53.4

found that the urban exceeds the rural rate by 19 per cent.

Cities. The correction for residence increases the rates of practically all cities. In the group

The high recorded death rate of Dutchess County is due to the large number of non-resident patients in the Samuel W. Bowne Memorial Hospital located in the town of Poughkeepsie.

AN EPIDEMIC OF VINCENT'S ANGINA*

By HAROLD J. HARRIS, M.D., WESTPORT, N. Y.

NO attempt is to be made to give a full dissertation on Vincent's angina. I want only to describe an epidemic of this infection occurring in my practice and to emphasize a virtually specific cure. As the epidemic is not yet over, I hope that this paper may be of some value. I claim no originality for the method, of course.

To compile an accurate list of all the cases I have seen within the past year would entail a tremendous amount of work. I am, therefore, estimating conservatively the total number of cases seen as about four hundred. This is an unprecedented number of cases in private practice. I do not recall more than a score of cases in the previous nine years.

The diagnosis in almost all of these cases was confirmed by direct smears examined at the State Laboratory at Albany, N. Y. A few typical cases were diagnosed and treated as Vincent's angina in spite of one or more negative smears. Cases of gingivitis due to pyorrhea in which the organisms of Vincent's angina happened to appear as a secondary or incidental infection were not classified as Vincent's angina nor treated in the same way.

There was one death in this series of cases—a neglected case in which the attending physician was called too late. This case I saw in consultation, but the infection had long since become generalized and treatment was without avail. There were many extremely ill patients of all ages, the youngest being six months and the oldest seventy-five.

The cases were classified as follows:

1. Those in which there were only greyish plugs in the crypts of otherwise normal looking tonsils.

2. Those in which one or both tonsils were simply congested and swollen.

3. Those in which there was ulceration of one or both tonsils, with anterior cervical adenitis.

4. Those in which there were scattered ulcers throughout the buccal mucous membrane, as the tonsillar pillars, the pharynx, the gums, the hard palate and the uvula—even rarely on the red border of the lips.

5. Those in which there were pre-ulcerative lesions on the mucous membrane of the mouth that resembled mucous patches or beginning "canker sores."

6. Those in which there was superficial or deep ulceration of the gums only, and

7. Those in which there was only a gingivitis.

Naturally, any or all of the above types of lesions occurred in some of the same patients.

Early in the epidemic diagnosis was difficult as

most cases then presented very mild and vague symptoms—moderate malaise, slight afternoon temperature rise and perhaps loss of weight, over a period of a month or two. In these cases the only findings were a few greyish plugs in the tonsillar crypts which might easily be mistaken for the ordinary plugs of detritus or food debris. The tonsils themselves were not reddened or swollen and there was only slight, if any, anterior cervical adenitis in these mild, early cases. Smears made from material obtained by firmly rotating a cotton swab over the tonsils were usually reported as showing a few or a moderate number or many fusiform bacilli and spirochaetes. The number of organisms found bore no relation to the severity of the infection in any of the series of cases.

The first of these mild cases I treated with the Kromayer lamp, using a pyorrhea quartz rod in contact with the tonsil and raying several areas of each tonsil every third day for three or four treatments which were usually sufficient to get rid of the organisms and cure the case. Along with any other method of treatment used, five grain potassium chlorate tablets were used in the mouth and as a solution for a mouth wash and gargle.

The more severe cases apparently had gone through the stage above described before they consulted me, as they gave histories of having felt mildly ill for from one to three months, had lost weight, and then had become rapidly worse with the onset of sore throat, anterior cervical adenitis and temperatures ranging from 101 to 104. One such case occurred in a woman of seventy-five; she was almost moribund when first seen with a temperature of 104, marked prostration, a mass of necrotic gum tissue, deep ulceration of both tonsils, and marked swelling of the anterior cervical glands. She also had a broncho-pneumonia, presumably due to the same infectious agent, which cleared up along with all the other areas (except the gums) within a week.

Most of these severe cases had advanced ulceration of the gums, and some had osteomyelitis of the alveolus about one or more teeth that ended with the spontaneous or surgical loss of one or many teeth. The throats of some bore such a marked resemblance to peritonsillar abscess that one would be tempted to incise except for lack of fluctuation and the knowledge gained by previous experience.

One of the characteristic symptoms of nearly every case in which the tonsils or tonsillar pillars were involved was pain radiating to the ear or just earache. In only one case was there any reddening of the drum. In another case a typical Vincent's infection of the gums and pharynx preceded a bilateral acute purulent otitis media; no

* Read before the Medical Society of the County of Essex, October 6, 1931.

organisms suggesting Vincent's were recovered from the purulent drainage

Some of the cases in which only the tonsils were involved presented very nice problems in diagnosis as they were indistinguishable from diphtheria or non-specific follicular tonsillitis. These cases had markedly swollen reddened tonsils studded with plugs of purulent exudate. They usually had high temperatures which helped to rule out diphtheria. If they failed to respond to treatment to the point of being actually well within forty-eight hours I learned to know that they were not Vincent's, regardless of what the smears might show. Within a week, recently, I saw four such cases, identical in practically every detail—two in adults and two in children. Cultures for Klebs-Loeffler bacilli were taken routinely as well as smears for the detection of organisms associated with Vincent's angina. Without waiting for reports intravenous and local treatments were begun and every patient was free of fever, sore throat and all local and general symptoms within forty-eight hours. All were much improved within twenty-four hours. One case seemed perfectly well except for a temperature of 99.6 and a very small patch of yellowish membrane involving one posterior tonsillar pillar. In the meantime both a positive diphtheria culture and organisms of Vincent's angina were reported. The other three had positive smears showing the organisms associated with Vincent's angina but negative diphtheria cultures. This child was then given diphtheria antitoxin and all symptoms disappeared within two more days. Thus, then, was a case of Vincent's angina co existing with diphtheria.

Those cases with only a few patches of reddened, swollen, easily bleeding gum tissue were more stubborn to cure than the other lesions, even though dentists co operated in their treatment.

One patient receiving a routine course of intravenous mercurous for an old-standing lues developed a Vincent's infection of the gums which might easily have been mistaken for a mercurial stomatitis.

The patient who died was a married woman of thirty-eight who had been vaguely ill at a hospital for months and had suddenly become worse on returning home. Her family doctor was not called until she was extremely ill with deep ulcerations studding her gums, lips, pharynx, hard palate, uvula, vagina and at least as far up the colon as could be seen with a sigmoidoscope. She was extremely ill with severe throat symptoms, a bloody mucoid diarrhea and a profuse blood-tinged purulent vaginal discharge. No organisms of any kind were isolated in this case which I saw in consultation a few days before her death. Local and intravenous treatment instituted by the attending physician were without avail. Clinically, this was Vincent's angina in its worst form. Treatment failed presumably because she was so

overwhelmed by her extensive involvement that the toxicity was too great for her to survive.

The treatment given routinely to every case, except the first few, was intravenous sulfarsphenamine in doses varying from 0.1 gm to 0.6 gm, depending upon the age. I soon found that I could almost promise a clinical cure after one treatment, that within twenty-four hours the patient would be much improved and within forty-eight hours clinically cured. The deep ulcerations would naturally take a few more days to heal. I can only recall two exceptions to this rule, in both of which there was deep ulceration about the teeth and of the mucosa over the hard palate, this probably is attributable to the lessened blood supply in these tissues. Early in the series many cases relapsed in two or three weeks after the one dose of sulfarsphenamine. After two injections, a week apart, were instituted as a routine only a few relapsed. Finally, I gave three doses of sulfarsphenamine to every case and none relapsed. In a few cases sulfarsphenamine in glycerine was applied locally to ulcerations of the gums.

Potassium chlorate tablets seemed to protect other members of the family, if used frequently—that is, a tablet kept in the mouth almost constantly. Also it was found that many mild cases of the patch type would clear up with no other treatment than potassium chlorate. Sodium perborate, plain or aromatised as in Vince, was used occasionally instead of potassium chlorate.

In no case was removal of tonsils necessary to cure the case clinically.

A few case histories, picked at random from my files, follow.

B G, Female, age 15, was first seen on September 6th 1931, complaining of sore throat and soreness of the gums of a week's duration. The tonsils had been cleanly removed several years before. There was ulceration of one anterior pillar, scattered ulcers over the posterior pharynx, gums and buccal aspect of the cheeks and lips with reddening of the gum margins in patches. Temperature was 100 and pulse 90. Smear showed a moderate number of fusiform bacilli but no spirochetes having the morphology of those associated with Vincent's angina. Sulfarsphenamine 0.3 gm was given intravenously and was repeated in four and eleven days. Improvement was not as prompt as expected after the first treatment but was rapid after the second. The ulcerations had healed and only a few patches of slightly reddened gums remained on September 17th.

H P, Male, age 10, was seen on September 2nd, 1931, because of the rapid development of sore throat in the preceding twenty-four hours. He had a marked bilateral anterior cervical adenitis, a temperature of 103 and both tonsils were greatly swollen and studded with plugs of purulent exudate. He complained of severe pain on swallowing and sharp pain radiating to one

ar. Sulfarsphenamine 0.25 gm. was given intravenously at once. The tonsils were less swollen and the exudate nearly gone next day and the temperature was 99.4. The tonsils were only lightly swollen and the exudate was gone forty-eight hours after the first treatment; temperature was 98 and the patient felt well. At the time of the second dose of sulpharsphenamine on September 9th a small yellowish patch of membrane on the right posterior pillar showed diphtheria bacilli. The patient felt entirely well. Five thousand units of diphtheria antitoxin were given intramuscularly. The patch of membrane disappeared within forty-eight hours and the temperature returned to normal. The third dose of sulfarsphenamine was given, as usual. The smear in this case showed a moderate number of fusiform bacilli and spirochetes having the morphology of those associated with Vincent's angina.

J. P., Male, age 25, was first seen on September 1st, 1931, complaining of a severe sore throat and swollen anterior cervical glands with sharp pains radiating to both ears, of twenty-four hours duration. There was extreme swelling of both tonsils which were thickly studded with a yellowish purulent exudate. He was extremely ill with a temperature of 103.6 and marked prostration. Smear showed no organisms having the morphology of those associated with Vincent's angina and culture showed no diphtheria bacilli. Sulfarsphenamine 0.4 gm. was given intravenously the same day. Twenty-four hours later the patient was out of bed, able to swallow solid food, the swelling and exudate had nearly disappeared and his temperature was 100. Within forty-eight hours he was well but still somewhat weak. Two more doses of sulfarsphenamine were given at weekly intervals to prevent recurrence.

N. D., Female, age 15, was first seen on February 2nd, 1931, at which time she complained of general malaise for the previous two months and a gradually increasing sore throat for the past two weeks, accompanied by progressive anterior cervical adenitis and soreness and bleeding of the gums. Her temperature was 100. Nothing was evident on examination of her throat and mouth except slight swelling of the tonsillar fossae (the tonsils were out), redness of several patches of gum margin and the adenitis. Smears and cultures were negative. Slight improvement occurred with the use of potassium chlorate as a gargle and

the tablets dissolved in the mouth but the gums became progressively worse with ulceration about the teeth. Sulfarsphenamine was not given until February 5th and was followed by prompt improvement in the glandular swelling and subsidence of the fever and malaise, but osteomyelitis of the alveoli had already progressed to the point where three teeth were loosened and were lifted out. Sulfarsphenamine was continued weekly and the gums healed promptly. Smears from the purulent exudate from the tooth sockets showed many of the spirochetes and fusiform bacilli of the type associated with Vincent's angina.

H. H. N., Female, age 65, had had medical treatment without relief of sore throat over a period of three weeks before I saw her on August 11th, 1931. She presented a moderately congested pharynx with reddening of both tonsils and a few areas of reddened gum margin. Aside from the sore throat her only complaint was occasional sharp, stabbing pain radiating from the throat to one or the other ear. Temperature was normal. Complete relief in forty-eight hours following the first dose of sulfarsphenamine of 0.4 gm. Although the throat looked normal a week later, two more doses were given as routine and potassium chlorate advised to prevent a possible flare-up of the gum infection. Smear showed a few spirochetes and fusiform bacilli having the morphology of those associated with Vincent's angina.

Comment: The treatment of choice in Vincent's angina seems to be three doses of one of the arsphenamines, along with the less important local measures. Probably the only advantages of sulpharsphenamine over arsphenamine or neoarsphenamine are the ability to give it intramuscularly to small children, and the lessened danger to tissues if it is spilled outside a vein.

It seems necessary to make clinical diagnoses and ignore laboratory smears under exceptional circumstances.

Diphtheria cultures are wise in every case, no matter how typical of Vincent's angina, as the two conditions may be clinically identical or may co-exist.

Pyorrhea, with which spirochetes and fusiform bacilli may be associated, should not be confused with clinical Vincent's angina.

Prompt and efficacious treatment with a potent remedy seems essential if severe illness or death is to be prevented in some cases.

CONTRALATERAL CAVERNOUS SINUS THROMBOSIS*

Following Furuncle of the External Auditory Canal: Recovery.

By ADOLPH WEIZENHOFFER, M.D., SCHENECTADY, N. Y.

THROMBOSIS of the cavernous sinus is a rare disease, about 350 cases having been reported since its first observation at autopsy about 100 years ago. In Johns Hopkins Hospital between 1889 and 1919, Chisolm and Watkins found the condition 8 times in 50,000 surgical cases, which averages 1 in 6,250. In the Ear and Throat Department of the Royal Infirmary at Edinburgh, between 1908 and 1925, Turner and Reynolds found 12 cases in 56,886 patients, an average of 1 in 4,740. There is no doubt that, when necropsy is not performed, many cases are overlooked due to the fact that the classical eye symptoms are not always present, the patient dying of a rapidly developing meningitis.

The cavernous sinus is a venous channel lying one on either side of the sella turcica. It is traversed by many fibrous bands, making its lumen very irregular. It is about 2 cm. long and 1 cm. wide, extending from the sphenoidal fissure to the tip of the petrous portion of the temporal bone. Within its inner wall lie the internal carotid artery and the sixth nerve, and in the outer wall, the third, fourth and the first two divisions of the fifth nerves. It is separated from the sphenoid sinus by a thin plate of bone, while the gasserian ganglion lies directly external to it. It is also in close relation to the optic nerve and chiasm and pituitary gland. It communicates directly or indirectly with the veins of the face, orbit, nose, mouth, throat, ear and scalp mostly by means of connecting or emissary veins. Anteriorly, the cavernous sinus receives the ophthalmic veins which drain the orbit, and posteriorly it opens into the superior and inferior petrosal sinuses, the former joining the knee of the lateral sinus, and the latter running into the jugular bulb. A connecting vein between the superior ophthalmic and the facial vein establishes communication between the cavernous sinus and the veins of the face. The absence of valves in these veins makes this communication more intimate. A few short veins run from the mucous membrane of the sphenoid air sinus into the cavernous sinus, and the superior ophthalmic receives branches from the ethmoid air sinuses. Passing through the foramen ovale, the foramen Vesalii and the middle lacerated foramen are veins connecting the cavernous sinus with the pterygoid and pharyngeal plexuses, which drain the mouth and throat. The carotid plexus surrounds the intracranial portion of the internal carotid artery and connects the internal jugular vein with the anterior portion of the cavernous sinus. By means of the mastoid emissary vein communica-

tion is established with the veins of the postauricular and occipital regions through the lateral sinus. It is also connected with the veins of the scalp by way of the diploic veins. The cavernous sinuses of both sides communicate with each other by means of the circular sinus, running in front of and behind the pituitary gland. The two inferior petrosal sinuses are united by the basilar sinus lying on the basilar portion of the occipital bone.

Infections of the middle ear, orbit and face are the origin of 75 percent of cases of cavernous sinus thrombosis. The most common organisms found are the streptococcus and the staphylococcus, the latter being present mostly when the original infection is small, localized and apparently unimportant.

Besides the symptoms of general sepsis, the cardinal diagnostic signs are produced by venous obstruction and pressure on adjacent nerves. The former causes exophthalmos, edema of the lids and chemosis of the conjunctiva, the latter, headache and eye pain due to irritation of the fifth nerve, paralysis of the eye muscles and rigidity and dilatation of the pupil from paralysis of the third, fourth and sixth nerves, and impairment of vision due to involvement of the second nerve. The second eye is almost always affected within 48 hours after the first, this being the most important differential sign distinguishing cavernous sinus thrombosis from orbital cellulitis. The symptoms develop more rapidly if thrombosis begins at the anterior end of the cavernous sinus than when coming from the petrosal end, due to the fact that in the latter case the collateral circulation has more time to establish itself. Death occurs mostly within a week after development of eye symptoms and is due to meningitis. Of 300 cases reported in the literature 23 or 7 percent got well. Eagleton reports 6 recoveries in 32 personal cases, which is 19 percent.

The treatment is mostly symptomatic with drainage of the focus of infection where possible. It is very important to avoid all mechanical and surgical interference in cases of furunculosis of the face especially of the nose and upper lip, before localization has taken place. To combat sepsis and increase resistance, the use of frequent small transfusions and the intravenous injection of mercurochrome, acriflavine or similar preparations, are recommended. The consensus of opinion points towards early diagnosis and prompt attack of the cavernous sinus itself. Eagleton claims that most of his cures were surgical, while others claim the contrary to be the case. The sinus should be approached through the orbit if the eye is destroyed or by the temporal route used

* Read before the Schenectady County Medical Society October 6, 1931.

in the gasserian ganglion operation, the latter being the most commonly used. Some operators employ the trans-sphenoidal or the maxillary route.

Mrs. N. S., aged 29, first seen March 28th, 1931, complained of pain in the right ear of two days' duration. Examination showed a slight blush in Shrapnell's membrane and along the handle of the malleus. The floor of the canal was somewhat reddened, but not swollen. Marked tenderness was elicited by pressure on the tragus, by traction on the pinna and on touching the canal floor with the probe or speculum. There was also some pain on moving the jaw. The mastoid was neither tender nor swollen. The ear was otherwise normal as were also the nose and throat. Wet dressings were applied.

March 29—Pain and tenderness worse and there was a little edema under the ear and a small abrasion but no swelling on the floor of the canal.

March 31—The edema spread under, behind and in front of the lobule. The patient claimed that the pain decreased following a feeling of "something giving" in the ear. The canal floor was red and slightly swollen. Toward the end of the day there was sudden pain in the left side of the chest and left shoulder accompanied by cough and expectoration of blood-tinged sputum. The temperature rose to 103.

April 1—The canal floor was incised but no pus was found. T. 104.6.

April 2—On slight pressure below the ear a drop of pus exuded from the cut in the canal floor. The incision was enlarged; but no more pus was found. The patient was removed to the Ellis Hospital.

April 3—The edema below the ear spread rapidly, so that in two days it had reached the clavicle. The whole right side of the neck was very red and tender and greatly indurated. The temptation to incise this area was very great; but as no fluctuation developed, this feeling was fortunately overcome.

April 4—An x-ray of the chest showed a shadow in the left lower pulmonary lobe. The blood count was W.B.C. 13,000, Polymorphonuclears 78%, lymphocytes 20%, eosinophiles 2%. The pulmonary infarct gave no trouble except pain on coughing, which disappeared in about three weeks, while that in the left shoulder caused only pain and limitation of motion and was gone in about four weeks without ever showing any redness or swelling.

April 5—The patient complained of pain in the left eye radiating to the occiput. The left upper lid became rapidly swollen so that the eye could not be opened. There was slight exophthalmos. Blood culture was positive for *Staphylococcus Aureus*.

April 6—There was marked edema of the left upper lid, proptosis of the eyeball and chemosis

of the conjunctiva. The right upper lid also began to swell.

April 7—The right eye was completely closed although the swelling was less than in the left. On forcibly opening the left eye the external rectus was found paralyzed. The temperature which previously fluctuated between 103 and 104, reached 105.4 on this day. The patient was restless and irrational, picked at the air and bed-clothes and voided involuntarily.

April 9—The swelling of the right eye began to subside as did also the induration in the lower part of the neck.

April 11—The patient opened the right eye partly, and the swelling in the left eye was diminishing. The temperature for the past two days slowly fell so that in a week it went down to 101. The first transfusion of 300 c.c. of citrated blood was given.

April 13—The right eye was normal and the swelling in the left was considerably reduced; but now paralysis of the levator could be noticed. All the other muscles supplied by the third nerve were normal. The retina was almost normal and vision was unimpaired.

April 14—The second transfusion was given. Repeated urinalyses showed a fraction of one percent of sugar, and nothing else. This disappeared after two weeks. There was no history of any previous glycosurea.

April 15—Patient complained for the first time of pain in the back of the neck.

April 16—Blood culture was negative after 48 hours incubation. There was a slight chill in the afternoon and the temperature rose to 103.

April 17—Patient was restless and irrational. Had another chill in the evening and the temperature rose to 104.4.

April 18—Patient more comfortable. Third transfusion given. Blood count: R.B.C. 3 million, hemoglobin 58%, W.B.C. 14,800, Polymorphonuclears 83%, lymphocytes 12%, eosinophiles 4%, basophiles 1%.

April 19 to 21—There was still pain in the back of the neck. The left pupil reacted to light and all the extrinsic eye muscles were normal except the levator and external rectus. Edema of the left upper lid was practically gone and exophthalmos had diminished.

April 22—Fourth transfusion given.

April 24—Blood count: R.B.C. 3,180,000, hemoglobin 54%, W.B.C. 14,300, Polymorphonuclears 79%, lymphocytes 18%. Blood culture was negative after 48 hours' incubation.

April 25—Fifth transfusion given.

April 28—Recurrence of pain in the left eye with headache and slight edema of the upper lid.

April 29—Pain and swelling better. Sixth transfusion given. Induration of the neck was almost gone.

May 2—During the past two weeks the tem-

perature slowly declined until it fell below 100. This continued for six days when suddenly on

May 9—The exophthalmos and swelling of the left upper lid increased, the eyeball became fixed, congestion of the conjunctiva returned, the pain in the neck grew worse and the temperature rose to 101.8. The patient didn't feel so well and was irrational at times. The knee-jerks were exaggerated. Kernig's sign was present on both sides, ankle clonus was present on the left side only, there was no Babinsky and the abdominals were present and equal.

May 11 and 12—The left pupil reacted very weakly. The patient vomited a little fluid before breakfast and was still irrational. The clonus was gone and the reflexes were quieter.

May 14—The patient complained of severe headache radiating from the back of the neck forward, but claimed that she was subject to such pains before her present illness. A cathartic gave relief. The left pupil was now dilated and rigid.

May 16—The temperature dropped to less than 100 and remained so during the rest of the illness, excepting for an occasional slight rise lasting a day.

May 19—Exophthalmos decreasing. Seventh and last transfusion given.

May 23—The patient left the hospital after a stay of 52 days, feeling better except for pain in the back of the neck, which was now worse on the right side. The left external rectus showed signs of beginning activity.

May 25 to 28—Pain in the left eye. Left upper lid swollen. Vomited three times.

May 29—Well except for occasional severe shooting pains in the left eye. Edema of left lid gone.

June 1—Shooting pains in both eyes. Right upper lid swollen.

June 3—Swelling of both eyelids gone. From now on there was progressive improvement of all the symptoms. The external rectus was the first to improve, then the levator followed by the other ocular muscles except the pupillary sphincter. The proptosis and edema gradually disappeared.

June 20—Patient still complained of pain in the back of the neck, confined chiefly to the region of the right trapezius muscle and shooting pains in the left eye.

July 16—For the past five days there has been no pain in the back of the neck. The left pupil reacted only very slightly to light. The patient felt well and was up and about.

July 21—The following is an extract of the report of Dr. O. J. Park on his retinal findings. At the beginning of the illness there was marked engorgement of the ciliary and fundus veins of the left eye with swelling of the disc. The right eye when it became involved, showed only a mild choking of the disc. On July 21 "her field of

vision showed an annular contraction of from 10 to 30 degrees with no enlargement of the blind spot. The venous engorgement in both fundi was practically nil."

Aug 7—The pupil reacted slightly to light and outward rotation of the left eye was incomplete. In attempting to look to the extreme left, vision became blurred.

Oct 3—Pupillary contraction of the left eye was improved. The external rectus was still weak.

Oct 6—Report of Dr. Park. Left eye, disc pale, fundus veins normal, external rectus weak, field contracted. Central vision and pupil normal. Right eye, disc slightly congested, field normal. Patient gained about 20 pounds.

The treatment was mostly symptomatic with the forcing of food and fluids. Seven transfusions of 300 cc of citrated blood were given. The only surgical treatment, namely, incision at the site of the focus of infection, was at the beginning of the illness, but after the blood stream had already been invaded.

The important features of this case are

1 The unusual location of the infective focus and its trivial nature.

2 The involvement of the cavernous sinus of the side opposite the focus previous to its invasion of the same side. The mechanics of the thrombosis is probably as follows. The infection entered the venous system at about the junction of the inferior petrosal with the jugular bulb, forming a retrograde thrombus up to the entrance of the basilar sinus into the petrosal. The blood flow being diverted at this point, carried an embolus across the basilar to the opposite inferior petrosal, where it found lodgment. Here another retrograde thrombus was formed which rapidly invaded the left cavernous sinus. Following this, the right cavernous sinus was involved through the circular sinus either by thrombosis or embolism. In the meantime the collateral circulation on the right side had sufficient time to establish itself, thus explaining the mildness and the short duration of the symptoms in the right eye. The subsidence of the circulatory symptoms in the left eye is due not only to the collateral circulation but in a large measure to a recanalization of the venous channels.

3 The gradual development of the ophthalmoplegia, beginning with the external rectus and levator, then involving the other external eye muscles and finally the pupillary sphincter, with return to normal in the same sequence.

4 The presence of a mild transient glycosuria which may have been due either to irritation of the pituitary or to the infection.

5 The undoubted low virulence of the infective organism. The septic symptoms were of a mild type, rigors, sweats and wide excursions of the temperature being rare.

6 The reappearance of eye symptoms on two

perature slowly declined until it fell below 100. This continued for six days when suddenly on

May 9—The exophthalmos and swelling of the left upper lid increased, the eyeball became fixed, congestion of the conjunctiva returned, the pain in the neck grew worse and the temperature rose to 101.8. The patient didn't feel so well and was irrational at times. The knee-jerks were exaggerated. Kernig's sign was present on both sides, ankle clonus was present on the left side only, there was no Babinsky and the abdominals were present and equal.

May 11 and 12—The left pupil reacted very weakly. The patient vomited a little fluid before breakfast and was still irrational. The clonus was gone and the reflexes were quieter.

May 14—The patient complained of severe headache radiating from the back of the neck forward; but claimed that she was subject to such pains before her present illness. A cathartic gave relief. The left pupil was now dilated and rigid.

May 16—The temperature dropped to less than 100, and remained so during the rest of the illness, excepting for an occasional slight rise lasting a day.

May 19—Exophthalmos decreasing. Seventh and last transfusion given.

May 23—The patient left the hospital after a stay of 52 days, feeling better except for pain in the back of the neck, which was now worse on the right side. The left external rectus showed signs of beginning activity.

May 25 to 28—Pain in the left eye. Left upper lid swollen. Vomited three times.

May 29—Well except for occasional severe shooting pains in the left eye. Edema of left lid gone.

June 1—Shooting pains in both eyes. Right upper lid swollen.

June 3—Swelling of both eyelids gone. From now on there was progressive improvement of all the symptoms. The external rectus was the first to improve, then the levator followed by the other ocular muscles except the pupillary sphincter. The proptosis and edema gradually disappeared.

June 20—Patient still complained of pain in the back of the neck, confined chiefly to the region of the right trapezius muscle, and shooting pains in the left eye.

July 16—For the past five days there has been no pain in the back of the neck. The left pupil reacted only very slightly to light. The patient felt well and was up and about.

July 21—The following is an extract of the report of Dr. O. J. Park on his retinal findings: At the beginning of the illness there was marked engorgement of the ciliary and fundus veins of the left eye with swelling of the disc. The right eye, when it became involved, showed only a mild choking of the disc. On July 21 "her field of

vision showed an annular contraction of from 10 to 30 degrees with no enlargement of the blind spot. The venous engorgement in both fundi was practically nil."

The treatment was mostly symptomatic with the forcing of food and fluids. Seven transfusions of 300 c.c. of citrated blood were given. The only surgical treatment, namely, incision at the site of the focus of infection, was at the beginning of the illness; but after the blood stream had already been invaded.

The important features of this case are:

1. The unusual location of the infective focus and its trivial nature.
2. The involvement of the cavernous sinus of the side opposite the focus previous to its invasion of the same side. The mechanics of the thrombosis is probably as follows: The infection entered the venous system at about the junction of the inferior petrosal with the jugular bulb, forming a retrograde thrombus up to the entrance of the basilar sinus into the petrosal. The blood flow being diverted at this point, carried an embolus across the basilar to the opposite inferior petrosal, where it found lodgment. Here another retrograde thrombus was formed which rapidly invaded the left cavernous sinus. Following this, the right cavernous sinus was involved through the circular sinus either by thrombosis or embolism. In the meantime the collateral circulation on the right side had sufficient time to establish itself, thus explaining the mildness and the short duration of the symptoms in the right eye. The subsidence of the circulatory symptoms in the left eye is due not only to the collateral circulation but in a large measure to a recanalization of the venous channels.
3. The gradual development of the ophthalmoplegia, beginning with the external rectus and levator, then involving the other external eye muscles and finally the pupillary sphincter, with return to normal in the same sequence.
4. The presence of a mild transient glycosuria which may have been due either to irritation of the pituitary or to the infection.
5. The undoubted low virulence of the infective organism. The septic symptoms were of a mild type; rigors, sweats and wide excursions of the temperature being rare.
6. The reappearance of eye symptoms.

occasions during the course of the illness; the first due probably to an extension of the clot, and the second, to a temporary inadequacy of the collateral circulation.

7. The absence of any visual impairment. Jansen proved by autopsy "that thrombosis of the cavernous sinus is possible with the absence of any change in the fundus, or any impairment of visual acuteness or of the function of the ocular muscles."

8. The long interval between the invasion of the blood stream and the beginning of eye symptoms; five days. This points to the posterior route, undoubtedly the inferior petrosal as the path of the thrombus.

9. The positive blood culture. This is very frequently negative.

10. The presence of ankle clonus for one day.

WHAT THE MEDICAL SOCIETY OF THE COUNTY OF MONROE IS DOING IN HEALTH EXAMINATION, ORGANIZATION AND PROGRESS

An address given before the Seventh District Branch of the Medical Society of the State of New York, at Iola Sanatorium, Rochester, N. Y., September 24th, 1931.

By SOL. J. APPELBAUM, M.D., ROCHESTER, N. Y.

From the Periodic Health Examination Committee, Medical Society of the County of Monroe.

IN the development of a program on behalf of any problem in any community, the environmental factors of the particular problem will always influence the character of the program. The problem itself, the size of the community, the individuals and organizations involved, the objects in view, must all be taken into consideration. Our program in Monroe County on behalf of periodic health examination was developed and modified with due consideration to the above factors.

During the past year the County Medical Society under the auspices of a Committee on Public Health and more directly under the auspices of a Sub-Committee on Health Education has been conducting a weekly Radio Broadcast. The central thought in all these broadcasts was the preservation of health, with stress on the value of periodic health examinations. There was considerable expression of interest on the part of the community to these messages as evidenced by the experience of many physicians, but the concrete results were not as great as anticipated. Early this year the Rochester Chamber of Commerce in a communication to the County Medical Society expressed an interest in periodic health examinations and sought to secure the cooperation of the Medical Society for an increased public interest in such examination. The Monroe County Medical Society had already for the past year been working in cooperation with the Tubercu-

culosis and Health Association to the extent that the Executive Secretary of the Tuberculosis and Health Association was the Acting Secretary of the Public Health Committee of the Monroe County Medical Society and of its sub-committees. At the very outset then the Medical Society in constructing its program could count on the support of these two lay organizations. Following the receipt of the communication from the Chamber of Commerce, on February 20th, a special committee of the Sub-Committee on Health Education was appointed for the purpose of developing a program in Monroe County with reference to periodic health examinations.

At its very first meeting this committee had the benefit of consultation with Dr. Iago Galston, Secretary of the Greater New York Committee on Health Examination, representing the five County Medical Societies of Metropolitan New York. The personnel of this committee is of interest. It consists of Dr. Benjamin J. Slater, President of the County Medical Society; Dr. John R. Williams, Chairman of the Committee on Public Relations; Dr. Edward G. Whipple, Chairman of the Committee on Public Health; Dr. William A. Sawyer, Chairman of the Sub-Committee on Health Education; Dr. Nathaniel W. Faxon, Director of the Strong Memorial Hospital; Dr. Albert D. Kaiser, President of the Tuberculosis and Health Association; and of the speaker as its Chairman. In its structure the Committee com-

prises those individuals whose advice and influence through their official positions in the County Medical Society and allied organizations of a medical character would be of greatest value to this movement. Through their official connections, they constitute a group which in itself can coordinate the interests of various committees in this special activity of the County Medical Society, it being the policy of the County Society that the activities of the other committees should give way to the program of the Committee on Periodic Health Examination.

After several conferences of this Committee, a number of recommendations were submitted to the Sub-Committee on Health Education. These recommendations were as follows:

First, that the County Medical Society establish headquarters; that it maintain a suitable office for the activities of the County Medical Society. This recommendation was made so that the County Medical Society could have a more definite entity; that anybody inquiring for the County Medical Society would have a definite place to go to, and that anybody wishing to telephone to the County Medical Society could on consulting the telephone directory find it listed there.

The second recommendation provided for the appointment of a permanent committee of seven (referred to above) to develop and conduct both an intensive preliminary and permanent program on behalf of periodic health examinations, which committee shall have a budget assigned to it and shall have authority to function without constant reference to higher authorities. This provision made the committee a primary committee of the Medical Society and gave it a free hand in the development of its program and the expenditure of its funds.

The third recommendation requested an appropriation of five hundred dollars (\$500) from the capital account of the Medical Society for the use of this Committee. This appropriation was granted by the County Medical Society at a meeting held on May 19th.

The fourth recommendation suggested the seeking of an additional two thousand dollars from other sources to cover an estimated budget from the period of October 1st to December 31st.

The fifth recommendation provided that after sufficient funds were secured that the Committee conduct an intensive preliminary health examination program to be followed later by a permanent program which was to be considered a regular function of the County Medical Society.

The sixth recommendation suggested securing the service of a part time executive secretary for this Committee and urged that the Committee be authorized to engage the services of such other personnel as might be necessary to carry on the program.

The seventh recommendation suggested that the permanent financing of this and other projects included in the Public Health Program of the County Medical Society be provided for after January 1, 1932, by increasing membership dues of the Medical Society of the County of Monroe to sixteen dollars. Dues at the present time are eleven dollars, ten dollars of which (as you know) goes to the State Society leaving only one dollar for local needs. This increase of membership dues would give the County Society approximately the twenty-three hundred dollars additional income needed to carry out the program as planned.

The eighth recommendation suggested seeking the cooperation of various civic and private organizations of a health, educational, labor, social service, and professional character, in bringing the message of health examination to the general public.

The ninth recommendation singled out the Rochester Chamber of Commerce, stating that the cooperation of the business interests represented by the Chamber was valuable and would be welcome.

The tenth recommendation suggested securing the cooperation of hospitals and dispensaries in providing limited facilities for the examination of indigent clients on proper refer in accordance with a definite understanding with the County Society.

The eleventh recommendation suggested that a series of bulletins to the profession on the subject of periodic health examination be inaugurated through the cooperation of the Tuberculosis and Health Association. For this purpose we were fortunate in being able to arrange for the printing of a Rochester edition of the *Health Examiner*, a monthly publication of the Greater New York Committee on Health Examination. We also were fortunate in being able to interest the Tuberculosis and Health Association in publishing two special reports, one of which lists the names of 252 practicing physicians who have signified their willingness to give basic health examinations.

The twelfth recommendation provided for securing the services of Dr. Iago Galdston, Secretary of the Greater New York Committee on Health Examination and Director of the Medical Information Bureau of the New York Academy of Medicine as consultant.

The Committee held its first meeting on March 13th with Dr. Galdston and Raymond H. Greenman, Executive Secretary of the Tuberculosis and Health Association, present. The above recommendations were adopted and Mr. Greenman was appointed Acting Secretary. They were presented to the Sub-Committee on Health Education on March 27th and were approved by it. They

were presented to the Committee on Public Health on April 1st, and were approved by that Committee. They were presented to the Comitia Minora on April 7th and again were approved. They were also considered and approved on April 22nd by the Directors of the Rochester Academy of Medicine who hold title to the Academy of Medicine building on Prince St., in so far as their approval was necessary for establishing Monroe County Society offices in that building.

A more detailed program was then developed with a desire to put into practice the recommendations reported. This program was divided into two sections. Section one concerns itself with activities within the medical profession. Our plans called for the completion of the activities in this section of the program before October 1st. However, vacation periods and the intense heat made this impossible. Nevertheless, the following has been accomplished: Arrangements have been made to open an office of the County Medical Society at 13 Prince Street. A budget of five hundred dollars was secured for the use of this Committee and the Committee is assured that funds will be provided to carry on until the first of the year. An intensive program has been conducted within the profession to familiarize it with the various questions and problems connected with health examinations. One hundred and twenty-six doctors in general practice and eighty-six physicians in the various fields of medical specialty including x-ray, eye, ear, nose, and throat, dermatology and genito-urinary, gynecology, orthopedics, surgery, neurology and pediatrics, were consulted in groups of about twenty for discussing program plans, examination procedure, record forms, refer methods, flexible fees, etc. Twelve such conferences were held, and in addition there were fourteen committee meetings. There was unanimous agreement that in order to make health examinations available to as large a section of the public as is possible it would be necessary that the fees for both basic, and special examinations when indicated, should be within the means of the individual. There was complete agreement that health examinations should be made available to the general public. There was full agreement with the thought that in so far as is possible health examinations be confined to private practice and that it is desirable that the general practitioner—family physician—should be prepared to make these examinations.

These various conceptions with reference to periodic health examinations had previously been agreed upon by the members of the Committee. It is of especial significance that they were approved of by more than three hundred members of the County Society (please recall the membership is just over four hundred), each of whom, under various circumstances, had an opportunity to express his opinion. As a matter of fact three

hundred and thirty-eight have agreed in writing to give health examinations. Although the program has not been officially approved by the County Society, nevertheless it has been approved by the individual members of the Society to the extent to which these three hundred and thirty-eight members accepted our invitations to be present at the various group meetings or gave us their approval in writing.

As part-time secretary, we have the services of the Executive Secretary of the Tuberculosis Association and make use of his clerical staff to the extent of our needs, making payment for the latter. To date the Rochester edition of the *Health Examiner* has been mailed every month to every practicing physician in the County. After the first of the year, our mailing list probably will include only such physicians who are sufficiently interested in health examinations as will subscribe to it at one dollar per year, this covering only the actual publication cost.

In conjunction with the Committee on Medical Education, a course of lectures on early diagnosis (of which Dr. Alvarez's lecture this afternoon is a part) has been arranged (for this week) in relationship to this program on periodic health examination.

Supplies, such as uniform examination records, cards suggesting examinations and report forms, are now in the process of preparation and will be made available to those desiring them.

Portions of this program have not yet been acted upon by the membership of the Society. Formal approval by the County Society of this entire program has not yet been given. We anticipate favorable action, which will include provision for the permanent financing of this and other educational projects in the public health program through an increase of dues. There has not been time as yet to discuss with the hospitals and dispensary authorities the problem of making provision for the examination of indigent clients. This opens up an entirely new field of procedure in the practice of medicine in Rochester. It is our purpose to attempt to arrange not only for this service but also to arrange for special examinations when such are indicated on refer of the individual by the examining physician. This arrangement, of course, would operate only with those who are unable to pay even very moderate fees for such special examinations. The patient and the report on his examination would be returned to the physician who requested the special examination.

If this procedure is put into practice there will be placed at the convenience of the examining physician all facilities for special examinations within the means of all individuals. This method of reference and report should tend to keep the public within the field of private practice rather than increase the present trend towards the insti-

tutionalizing and socializing of medical practice. This procedure should also correct the too common conception that complete examinations—that is a basic examination and such indicated special examinations—can only be made in clinics, can not be made in the offices of practicing physicians.

As a part of this program for the purpose of improving the quality of the work done, it is hoped that arrangements may be made with the Medical School of the University of Rochester to give post-graduate instruction in the use of various diagnostic instruments and diagnostic procedures.

In furthering a program for relating the services of the Medical and Dental professions in a coordinated educational program the Rochester Dental Society has been invited to and has accepted an important place in the field of educating the public in regard to the value of Periodic Health Examination. Through the radio, in their offices, to their patients, and through literature the Dental Society through a recently appointed educational committee, will work in close cooperation with a similar committee of the Medical Society on behalf of periodic health examinations. One special feature of this program is the loose leaf book of sixty one radio broadcasts—one hundred and forty three copies of which are in the hands of doctors, dentists, school instructors, agencies and public libraries of the City and in the hospitals and dispensaries. This has proved to be of value as a means of systematic health education.

The second section of this program consists almost entirely of publicity directed to the general public. This portion of the program will be carried out by the Chamber of Commerce and the Tuberculosis and Health Association in consultation however, with the Medical Society. This division of work will no doubt obviate much criticism of the medical profession. The public is too ready to attribute commercial motives to any propaganda regardless of how much it benefits through this propaganda.

The objectives of this program are *first* to impress upon the public mind the importance of periodic health examinations and *second* to point out that the family physician is best qualified to make such examinations. His intimate knowledge of the individual's history and environment places him in a position where he usually can interpret better the individual's symptoms and can evaluate them more correctly. The public will be reached through circularization of the membership of many civic fraternal labor and educational organizations, issuance of special articles in specialized publications, through short talks to various groups through radio broadcasting, special exhibits, newspaper releases and advertising, special educational motion pictures and distribution of special prepared leaflets, notably "Pity the

Poor Ostrich." This program will be officially inaugurated with a public dinner at the Chamber of Commerce on September 29th under the joint auspices of the Chamber of Commerce, Tuberculosis and Health Association and the County Medical Society of Monroe. Just a week ago 25,000 leaflets were distributed by the Tuberculosis and Health Association at an exhibit at the Rochester Exposition.

I have so far discussed the organization of this program, its progress and our hopes of what can be done to further it. To conclude at this point would necessarily leave out of consideration what in my opinion is the most important question with reference to this entire activity. That is, what is the value of all this work? This activity on the part of the Medical Society in the *first place* has a great value to the public because it gives to it a service which the public needs and is not now getting. It also has great importance to the community in that it signallizes the joint action of the medical profession and lay groups in a matter of importance to the public. I think it is not necessary at this time to go into the question of the value of periodic health examinations. The time allotted to this paper does not permit so doing and I shall have to assume that you all recognize its value and importance. Valuable as this type of activity may be to the public it is of even greater value to organized medicine. Too long has organized medicine stood by quietly while official and voluntary health organizations undertook the entire burden of solving medical public problems. In the solution of such problems by lay organizations the interests of the medical profession and often thereby the true and deeper interests of the public often were overlooked. A point of view foreign to the medical profession often is the motivating power in such solutions of medical problems and consequently the result is not as we would like it. As long as the medical profession holds itself aloof from medical problems in which the public is interested, just so long will the leadership which properly belongs to the medical profession naturally be assumed by others.

In recent years the Medical Society of the County of Monroe has shown an increasing interest in the public health problems of the County of Monroe and the City of Rochester. It is developing a community consciousness. The Society has demonstrated an interest, constructive in character, on the question of the County Health Unit.

The Committee on Public Relations under the chairmanship of Dr. John R. Williams is responsible for initiating a survey on the hospital needs of Rochester with the object in view of coordinating the hospital facilities to the community needs.

Under the constructive leadership of Dr. I. G.

Whipple, an organization of sixty-two physicians has been created known as the Public Health Committee. Ten standing sub-committees made up of physicians in the various fields of medical specialty have considered the public health needs and the programs of different agencies in the City and County. The County Society, through the activities of this Committee has representation on the board of directors of the voluntary health agencies, the Council of Social Agencies, the Nursing Association, etc., giving medical counsel and advice. Dr. Whipple has unstintingly given of his time to attend all sub-committee meetings and has devoted a great deal of thought to the programs of his committees.

The Committee on Child Welfare under Dr. John Aikman has assisted in the development of a child health consultation program for the rural part of Monroe County, and has taken steps in conformity with the plans of our local Health Bureau to aid in insuring the protection of the community in the threatened epidemics of measles and poliomyelitis.

The Diphtheria Prevention Committee under Dr. George S. Price has sponsored an educational program and has assisted in the immunization of 55% of the children of pre-school age in rural Monroe County.

The Social Hygiene Committee under Dr. Frederick Garlick has sponsored a carefully planned educational program recommended by the State Medical Society.

The Maternity Protection Committee under Dr. Lawrence E. McCaffery has requested the Council of Social Agencies to make a study of the maternity protection needs of the City and has sponsored a special observance of Mother's Day.

The Tuberculosis Committee under Dr. John J. Lloyd has sponsored a fact finding study made by the Tuberculosis and Health Association and has cooperated in the splendid program undertaken by Iola Sanatorium to x-ray all the school children in Monroe County outside of Rochester.

The Committee on Mental Hygiene under the chairmanship of Dr. Kirby Collier has advocated the establishment of a psychiatric ward in one of our general hospitals. This would make possible the admission of mental cases into a general hospital for a limited period of time and so often avoid the distressing ordeal of a legal commitment.

The Cancer Committee under the chairmanship of Dr. John M. Swan has furnished personnel for the maintenance of a Cancer Clinic in the headquarters of the Public Health Nursing Association, and through the Tuberculosis and Health Association has circularized the medical profession in regard to the early diagnosis of cancer.

The Cardiac Committee under Dr. Rufus B. Crain has made a survey of the cardiac cases in

the high schools of Rochester. The Committee on Health Education under the able chairmanship of Dr. William A. Sawyer has been conducting for the past year and a half a weekly radio broadcast that has proven of considerable value not only to the County of Monroe but to every place where the radio carried the weekly messages of advice on how to guard health and keep well. Of the more than 12,000 requests received for copies of these talks, a majority have come from rural residents in the territory included in the 7th District. From comments made not only by local physicians but also physicians in various parts of the State where the public listened-in we know that many individuals by following the advice given not only preserved their health but sometimes were led to life-saving measures.

In our Committee activities on behalf of periodic health examinations, we are also fulfilling a public need. The general public is being educated to ask for this service. The thinking part of the public has been asking for it for a number of years.

The life insurance companies, our large industrial plants, our public schools, our chambers of commerce and voluntary health organizations until now have been responsible almost entirely for encouraging this movement. If the medical profession does not become responsive to this need then these various lay organizations will without doubt devise some other means than that of private practice whereby this need may be fulfilled.

We have been told that the Monroe County Medical Society has a comprehensive public health program. With all due modesty, we are beginning to believe it ourselves. If in developing a similar program we can be of any assistance to other county societies we shall be pleased to make available to them our experience.

SUPPLEMENTARY NOTE

At a special meeting of the County Medical Society held September 25th the above recommendations of the Committee on Periodic Health Examination were approved. Approval was also voted for the recommended increase in dues for the year 1933, and for an assessment of \$5.00 to finance the Society until then.

An agreement was reached with the hospital and dispensary authorities which provides for the examination of the apparently well individual, and for special examinations only when they are requested by the practicing physician. It is understood that both the patient and report on the findings of the examination will be referred to the practicing physician when he so requests.

At its October meeting the County Medical Society approved an appropriation of \$2,400 for the Public Health, Post Graduate Instruction, and Periodic Health Examination Committees,

ENDOSCOPIC AIDS IN DIAGNOSIS*

By JOSEPH W. MILLER, M.D., NEW YORK, N. Y.

From the Department of Laryngology and Peroral Endoscopy, Beth Israel Hospital, New York City; service of Samuel J. Kopetzky.

PERORAL endoscopy is now playing an important part in the diagnosis and treatment of diseases of the larynx, lungs, mediastinum and esophagus. A realization of its possibilities for exact diagnosis or confirmatory observations that will bear out other clinical findings is important. It is not merely a method for the direct extraction of foreign bodies or a mysterious sleight of hand procedure. Numerous case reports will attest to its decisive value in many doubtful cases.

In a masterful review of the subject of peroral endoscopy, Andre Soulas refers to the remarkable developments in technique that have justified the practitioner in resorting without hesitation to the bronchoscopist for both the diagnosis and treatment of pulmonary disease. He refers to the diagnosis by bronchoscopy of compression stenosis of the trachea due to aneurysm, mediastinal tumors, substernal goiter, thymic hypertrophy, adenopathy, tracheal urticaria, benign and malignant tumors of the bronchi and lungs, gunnams and cancer of the adjacent portion of the esophagus.

In children indirect examination of the larynx is impossible and one must resort to direct laryngoscopy and no child is too sick for such an examination. A correct diagnosis here is imperative and vital.

Diseases of the larynx may be the causes of hoarseness or respiratory difficulty or dysphagia—chronic inflammation, tumors, various types of muscular pareses or paralysis, or foreign bodies may be the underlying irritant. Hysteria, in the form of motor or sensory neurosis may simulate disease. Obscure pains in the larynx may result from ulcerations, tuberculous or otherwise. Respiratory difficulties may be caused by neoplasms malignant or benign, or in acute cases a diphtheritic membrane or edema. Direct laryngoscopy is now the accepted method for removal of diphtheritic membranes.

Neoplasms of the larynx may be benign or malignant. The malignant may be intrinsic or extrinsic and infiltrating. Under direct laryngoscopy the extent of the lesion may be more accurately observed and biopsy easily accomplished. Hysteria, a frequent cause of hoarseness, particularly in adolescent girls and neurotic women is best examined by direct laryngoscopy to exclude with certainty any pathology in the larynx and it often also serves as a therapeutic measure. The various forms of muscular pareses are due to either muscular changes resulting from abuse or misuse of the voice or chronic inflammation

usually the result of chronic suppuration in the nasal accessory sinuses. The true paralyses are due to injury or pressure on the recurrent laryngeal nerve. The cause may be in the mediastinum, or an hypertrophied thyroid, enlarged lymphnodes along the course of the nerves or trauma after thyroidectomy.

In the summer of 1929 I had occasion to observe two cases of laryngeal diphtheria that were admitted to the hospital with an entirely different diagnosis. Severe dyspnea in both infants prompted me to examine the larynx directly. False membranes were found and removed by suction, the children injected with anti-toxin and then removed to the Willard Parker Hospital.

The lungs may be the seat of various diseases that give rise to coughing, dyspnea, asthmatic attacks or pains in the chest. The bronchi are subject to chronic inflammations, tumors, foreign bodies, strictures, dilatations, retractions, occlusions, varicosities and ulcerations which have a common symptomatology. General clinical examination may not yield a definite diagnosis and so bronchoscopy easily proves its value. In diseases of the lung parenchyma itself evidence may be found in the bronchi, in the character of the secretions or as changes in the form or shape of the lumina carina and secondary bifurcations.

Bronchiectasis is very satisfactorily demonstrated after lipiodol injection into the tracheo-bronchial tree through the bronchoscope. The Roentgen picture will then show characteristic dilatations of the bronchioles. Especially is this method valuable in the left chest where the cardiac shadow may obstruct or hide from view the bronchial dilatations in an ordinary chest plate.

Many cases of asthma are erroneously treated as such and one often finds with the aid of bronchoscopy lesions in the tracheo-bronchial passages such as polypi, strictures, tenacious secretions, a non opaque foreign body or a bronchogenic tumor. All these conditions may give symptoms of asthma and true asthmatic attacks. It might be well for every physician to bear in mind Dr. Chevalier Jackson's wise and timely warning that "all is not asthma that wheezes."

Pneumonias, particularly in children which run a bizarre course may result from the presence of a foreign body. Bronchoscopy is the only method that will settle this definitely, and removal of the foreign body will give a brilliant result.

Such a case came to my observation recently. A boy, four years of age was admitted with the diagnosis of pneumonia and treated for this condition for five weeks. The X-Ray films of his chest revealed changes suggestive of pneumonia.

* Read before the Eastern Medical Society at Hotel Brevort, New York City, on March 13, 1931.

In only two of the numerous plates did the Radiologist report a suspicion of a foreign body. That this made no impression on the medical attending is evident from the fact that he did not request a bronchoscopy. The request, however, was made by the bronchoscopic department through my associate Dr. M. L. Harris, on information I obtained from a friend of the family that the child "swallowed" a piece of tin foil just before he took sick with pneumonia. Ten days later we were requested to perform bronchoscopy. This was carried out promptly without anesthesia either general or local and a metallic foreign body was sighted at the bottom of the left main bronchus and removed. This turned out to be a rolled-up piece of aluminum foil which the boy removed from a piece of chocolate. The Roentgenologist then informed us that aluminum does not throw a shadow to the X-Rays. He should, therefore, be congratulated in this case for his fine work and interpretation.

The esophagus is the channel through which all our nutritives must pass and it is a frequent seat of disease. Foreign bodies, dilatations and diverticula, spasms and peptic ulcers, tumors and scars following previous injuries may give rise to pain and difficult swallowing and disturbances in nutrition. Clinically they may give rise to similar symptoms; but the etiology being different, intelligent treatment demands an exact diagnosis. Here esophagoscopy is invaluable.

Foreign bodies in the esophagus may come in every shape or form that man has taken into his mouth. These may cause partial or complete obstruction most likely in the crico-pharyngeus region and, if not relieved will cause ulceration, abscess formation and perforation into the neck or mediastinum. Usually there is a history and a Roentgen picture may frequently help in making the diagnosis, but the esophagoscope is absolute not only in establishing a correct diagnosis but in determining the exact location, size, shape and character of the invader. Removal, of course, must be done through the esophagoscope.

Tumors, benign or malignant can be demonstrated by esophagoscopy and the diagnosis substantiated by biopsy. Spasm of the esophagus often simulates obstruction by neoplasms and here direct observation is important. Ulcers too can simulate tumors clinically, and particularly peptic ulcers in the lower esophagus. Esophageal strictures due to scars, resulting from chemical burns are easily demonstrated with esophagoscopy and,

at the same time this is the safest way to start dilatation under direct vision.

The importance of endoscopy as an aid in diagnosis of esophageal disease is best illustrated by the following case. A white adult male 49 years of age was admitted to the Beth Israel Hospital on the service of Dr. Kopetzky on July 23rd 1929 with a diagnosis of carcinoma of the esophagus. His history briefly is as follows:—Two and one-half years before admission first noticed dull pain over sternum at level of 5th rib. Vomited solid food. Gradually pain and vomiting became more severe. One year before admission began to lose weight and soon began to vomit liquids too. He lost sixty pounds in one year reducing from 200 to 140. The pain was dull and did not radiate and there was a progressive loss of strength. He was operated 14 weeks prior to admission at another hospital for gastrostomy so that he could be fed through a gastric fistula. Three weeks later he was sent to the Memorial Hospital for the express purpose of receiving deep Roentgen therapy. To the Beth Israel Hospital he was merely sent in to end his last few weeks on earth in comfort among congenial people of his own choosing.

The X-Ray report before esophagoscopy reads as follows:—There is a complete obstruction at the lower end of the esophagus. There is a dilatation of the esophagus above the obstruction. There is a new growth at the lower end of the esophagus.

Esophagoscopy on July 25th 1929 revealed a cardiospasm or as Jackson calls it, preventriculosis, of the lower end of the esophagus just below the diaphragmatic constriction. No sign of a tumor nor other pathology was encountered. When this was called to the attention of the roentgenologist, the X-Ray report following the esophagoscopy read as follows—Examination of the esophagus shows a marked dilatation of the esophagus and a point of narrowing at the cardia. The appearance being suggestive of a cardiospasm. There is no new growth of the esophagus.

Retrograde dilatation was promptly instituted followed by dilatation from above with the Plummer Hydrostatic Cardiospasm Dilator. Soon liquids made their way down the esophagus and after a few dilatations solid food made its way down into the stomach. The gastric fistula was made to heal. He then began to gain weight and strength rapidly and made an uneventful recovery.

NEW YORK STATE JOURNAL OF MEDICINE

Annual meeting, Hotel Statler, Buffalo, N. Y., May 23-25, 1932

HOUSE OF DELEGATES

The special meeting of the House of Delegates of the Medical Society of the State of New York was held in the Hotel Ten Eyck, Albany, on Thursday, January 14, 1932, as announced in the Journal of December fifteenth and January first. The object of the meeting was to discuss the general attitude of the medical profession toward Governor Roosevelt's Health Commission whose studies and suggestions were printed in the Jour-

nal of October first, 1931. The Joint Committee appointed to consider the Commission's recommendations, made a formal presentation of its report which had already been printed in the Journal of January first. The discussions on the floor of the House were concise and pointed, and the result was the adoption of the entire report. The minutes of the House of Delegates will be printed in the Journal of February fifteenth.

MEDICINE AND GEOLOGY

A list of one hundred American physicians, who were also geologists of note, is contained in an article entitled "The Relation of Physicians to Early American Geology," by Dr. William Browning of Brooklyn, in the *Annals of Medical History*, New Series, Vol. 3, No. 5, September, 1931. The list begins with Dr. William Baylies, who was born in 1743, and wrote on the geology of Martha's Vineyard; and ends with Dr. Robert Bell, who was born in 1841, and was chief of the Canadian Geological Survey. The list was compiled principally from the names of geologists contained in standard encyclopedias; and Dr. Browning reaches the remarkable conclusion that physicians constituted about fifty per cent of the American workers in geology when that science was in its stage of development.

Dr. Browning gives some natural reasons that physicians should be pioneers in geology. They constituted almost the only group of Americans who were trained observers and had a background of scientific education. They were constantly travelling over the extensive areas of their practice, and they were the recognized authorities to whom the people looked for explanations of strange objects or phenomena. Then, too, physicians were often attached to gangs of surveyors and road builders, and had abundant opportunities for making discoveries. When geology emerged from the stage of observations into that of scientific coordination with other sciences such as chemistry, physics, botany, and zoology, many physicians gave up their medical practices and became professional geologists, largely in governmental positions.

The thirteenth physician on Dr. Browning's list of geologists was Dr. John Steele, who was born in Massachusetts in 1780, practiced medicine in Saratoga County, and served as president of the Medical Society of the State of New York during the years 1834 and 1835. He wrote on the geology of Saratoga County, and doubtless obtained his facts from observations made during his medical visits.

A search of the record of Dr. Steele in the first book of the Transactions of the Medical Society of the State of New York disclosed the name of Dr. John Stearns, who also practiced medicine in Saratoga County, and was elected the first secretary of the Medical Society of the State of New York and served for seven years. He was made a permanent member of the State Society in 1814, only two being so honored each year. He was elected president of the State Society in 1817 and served four terms.

The record of the connection of Dr. Stearns with geology begins in February, 1808, when he with six other physicians "Reported a topographical and geological description of their sev-

eral counties together with the diseases prevalent in the same," in accordance with a provision of the by-laws adopted at the organization meeting of the Society on the first Tuesday in February, 1807. The records show that reports from the following counties were given during the first six years of the existence of the State Society:

Montgomery, by Dr. Alexander Sheldon.
Orange, by Dr. David R. Arnell.
Dutchess, by Dr. William Wheeler.
Saratoga, by Dr. John Stearns.
Jefferson, by Dr. Hugh Anderson.
Clinton, by Dr. Horatio Powell.
Westchester, by Dr. Lyman Cook.
Essex, by Dr. Alexander Morse.
Ontario, by Dr. Renbey Hart.
Chenango, by Dr. Henry Mitchell.

The records of the meeting of February 5, 1811, show the following entry:

"The Prize Medal for the best Dissertation on the Topography, Geology, Mineralogy, and Medical History of any County in the State of New York was adjudged to Doct. Stearns of Saratoga." This was one of three medals which had been authorized at the annual meeting in February, 1808, the first after the organization meeting a year previously. The second medal was offered for the next best dissertation, or survey, of the same subject, and the third medal was for "The best dissertation on the causes and best method of preventing and of curing the typhus mitior or low, nervous fever, which prevails in the different counties of the State."

The presidential address of Dr. Stearns on February 2, 1819, at the end of his second year in office, was largely on the subject of geology and illustrates the embryonic state of the science in that day, when the book of Genesis was accepted as the literal explanation of Noah's flood as well as the Creation. After mentioning the geological work of Dr. Mitchell and of M'Clure, he describes the work of Cuvier and says:

"It may be interesting to remark the coincidence of the discoveries of this indefatigable geologist, and the improved theory of this science, with the Mosaic history of the creation and deluge.

"The important discoveries of Cuvier, afford strong facts to prove that the earth had experienced some extensive revolutions long before it was inhabited by man, and that the last great convulsion perfectly corresponded in time with the account of the deluge. This evidence was chiefly deduced from the vertical position of certain strata, the fossil remains of animals, and the entire bodies of the rhinoceros and elephant being found so far beneath the surface, as to require the lapse of four thousand years to cover them to

that depth. While Cuvier adduces the latter fact as evidence of the suddenness of the convulsion, Kirwan cites it to prove that the deluge was caused by the vast waters of the Southern Ocean bursting upon the north and thus overwhelming the world. His reasons are, that the rhinoceros, an inhabitant of warm climates, was found in the frozen regions of Siberia two hundred miles from the sea, surrounded by marine exuviae of tropical origin, and thence concludes that he was driven by the immense force of the flood from his native clime, and deposited near those mountains of the north, which opposed a barrier to this impetuous torrent. In confirmation of this hypothesis, he minutely traces the impressions which this course of the waters would necessarily produce upon the surface of the earth. He thus accounts for the conical shape of the two continents, and of all islands with their apex to the south, which were most exposed to the ravages of this eruption, exhibiting excavations on one side, and corresponding projections on the other, according to the flux and reflux of this vast current. To the same cause he imputes the barren deserts of Africa, and the fertility of that mountainous section of country which arrested its progress towards the north.

"Whether this grand precipitation was miraculously completed in the definite period of a single day, or whether it was left to the slow operation of a natural process, and by the first day of creation, as on other occasions was therefore intended a figurative representation of one thousand years, are questions which we are unable to solve."

After a page or two of conjectures of extreme interest, Dr Stearns comments on the relation of geology to infectious diseases and says:

"Although it is a common opinion that epidemic diseases originate from some peculiar change in the atmosphere, few have ever suspected, and none actually investigated, the cause of

those changes beneath the surface of the earth. Physicians have generally been satisfied with ascribing epidemic diseases to the vicissitudes of weather, to contagion, or to infectious miasmata, arising from the decomposition of animal or vegetable substances. But facts are at variance with the former, and the latter are too limited in their operation to extend their influence over a whole continent. Mr Webster (who wrote a book on epidemiology, as well as a dictionary) has, with great industry and perseverance, drawn from history such a compilation of facts as to induce a belief that the real source of many epidemic diseases must be traced to the interior of the earth. That subterranean fires are continually decomposing the materials of that region and occasionally ejecting their gaseous results into the atmosphere, are facts corroborated by history, and by every volcanic eruption upon the surface. To this source we must impute the emission of a dense vapor which sometimes overspreads the horizon with darkness producing those dark days which philosophers have been unable to explain. The conjoined influence of the celestial bodies, in aiding this effect, and also in the production of earthquakes and volcanoes, must be admitted by all who adopt the Newtonian theory of tides. Whether this influence is exerted through the medium of gravitation or electricity, is still enveloped in the arcana of nature. But is a historical fact, that such phenomena are succeeded by epidemic pestilential diseases, and probably produced by the deleterious gas which accompanies such eruptions. This may be the origin of those epidemics which, from the plague of Athens to the yellow fever of New York have been the subject of controversy in all ages."

It is probable that Dr Stearns was the source of inspiration of his professional colleague, Dr Steele, who achieved the recognition of encyclopedists in the field of geology.

LOOKING BACKWARD

This Journal Twenty-Five Years Ago

Executive Officers The Medical Society of the State of New York makes a distinction between its officers and its paid executives. The earliest mention of this distinction seems to have been made by Dr Joseph D Bryant the first President of the Annuitant State Society, who referred to the subject in his exaugural address delivered on January 29, 1907. This reference was printed in this Journal of February, 1907.

The editorial policy of a journal of mutual constituent ownership like this of ours, should be guided by the composite wisdom of an impar-

tial committee chosen for the purpose, rather than by the notions of the editor himself, as in the instance of personal proprietorship. Prompted by this belief, the President declined to appoint on the Publication Committee the Editor of the Journal. In my opinion the salaried agents of the Society ought not for apparently obvious reasons, to be entitled to membership in the executive bodies which regulate their compensation or determine their policies of action. Other and wiser means of conference than this can easily be determined."

MEDICAL PROGRESS

Resuscitation from Asphyxia and Treatment of Secondary Pneumonia by Inhalation of CO₂.—Yandell Henderson, writing in the *British Medical Journal*, October 17, 1931, ii, 3693, says it is not enough to resuscitate a man from drowning, asphyxia from carbon monoxide gas, or other accident, and after surgical anesthesia, if he is to die a few days later from secondary pneumonia. The pneumonia may be prevented by the method which he describes. When a mixture of oxygen and carbon dioxide is administered after a short but intense asphyxia the effects are truly extraordinary. After longer but less intense asphyxias, resuscitation is not so rapid, but the subsequent development of pneumonia is prevented. It has always been supposed that there must be an overpowering excess of carbon dioxide in the blood in cases of asphyxia. Experience now demonstrates that it is not excess of carbon dioxide, but deficiency of oxygen, that induces depression of the respiratory center. The inactive center promptly becomes active again if the amount of carbon dioxide supplied to it is sufficient. When the normal 5 percent carbon dioxide is insufficient to stimulate, an increase to 7, 10, or even higher percentages of carbon dioxide may be needed. The inhalation of a mixture of oxygen and carbon dioxide is initiated under prone-pressure artificial respiration.

This form of inhalation is not only applicable to asphyxias due to drowning, carbon monoxide poisoning and other accidents, but is fast replacing the old barbarous and often ineffective methods of resuscitation of the newborn. As much carbon dioxide may be used as is necessary, usually 7 per cent with oxygen. A large part of the neo-natal mortality is a consequence of continuing atelectasis, which favors the development of pneumonia in undilated areas of the lungs. Combining this fact with other evidence, Henderson suggests that the lungs of every new-born child should be fully dilated by inhalation of carbon dioxide in the first few days of life. In the operating room it has been noted, that patients who receive this inhalation after operations remain free from postoperative pneumonia. Respiration is closely associated with the tonus of the muscles, especially those of the thorax. Depressed breathing and low tonus permit collapse of part or the whole of a lung. Then, if infection is present pneumonia develops. If respiration and muscle tonus are stimulated by inhalation of carbon dioxide the lungs will be kept open and development of pneumonia will be prevented.

Appendicitis at an Advanced Age.—On the basis of a study of 31 cases, R. Patry and W. Heer say that appendicitis in persons of advanced age exhibits a considerably higher mortality than at an earlier period of life. Nearly two-thirds of the cases were recurrences. The diagnosis is frequently made more difficult by the fact that the clinical picture is veiled. Operation often presents technical difficulties, and in addition the surgeon has to take into account the waning powers of resistance of the aging organism. In advanced cases operation must be carried out without delay, but may be postponed in cases that tend to come to a standstill or promise complete recovery. The impression is given that the aging organism reacts less to the attack than that of a youthful person. The bodily temperature nearly always remains within subfebrile limits. The general condition requires special attention, since we have to reckon with adiposity, hypertonia, emphysema and chronic catarrhs of the respiratory organs, with myocardial affections, cirrhotic processes, diabetes, and increased tendency to embolism. Local symptoms, sensitivity, and tension of the abdominal wall are frequently less in evidence than in youthful subjects. This is due to the decreased reaction of the aging organism and in some cases to adiposity. The tendency of the disease to run a milder course makes the diagnosis more difficult in many cases. The differential diagnosis also presents greater difficulty, since in the later years of life other ailments, such as pancreatitis, cholecystitis, perforation of the stomach, and other acute affections of the abdominal cavity run concurrently with appendicitis. Relatively frequent is a masked appendicitis, simulating a strangulated hernia. All the 31 patients were operated on. In 19 there were found adhesions of the appendix and its environs. In nearly two-thirds of these there were signs of an earlier inflammatory illness, revealing that this attack was a recurrence, just as the history had indicated. Nine were cases of perforation, and 14 of gangrenous appendicitis. Points of importance are the making of an early diagnosis, the determination of the precise indications for operative intervention, and the making of a large incision. Good supervision makes for a rapid and safe operation.—*Schweizerische medizinische Wochenschrift*, September 12, 1931.

Animal Parasites and Appendicitis.—Assertions made by certain authors to the effect that parasitic worms may cause a true appendicitis led Vittorio Vanni to make a systematic examination of 200 appendices that had been surgically re-

moved, with a view to getting some idea of the frequency of worms in this organ. Only 7 of these appendices were found to contain parasites or eggs of parasites, as follows: Adult *Oxyuris vermicularis*, 7 times (35 per cent of cases), *Trichocephalus trichiurus*, eggs only, in 1 case (0.5 per cent); *Ascaris lumbricoides*, eggs only, in 1 case (0.5 per cent), *Entamoeba dysenteriae*, in 1 case (0.5 per cent). *Oxyuris* is the parasite which, in addition to its greater frequency in the appendix, has the property of becoming localized in the mucous membrane, in the form both of eggs and of adult worms. It does not cause the anatomic changes of classical appendicitis, but produces hemorrhages and constant local infiltration of eosinophile elements. This local eosinophilia must be regarded as a phenomenon of local anaphylaxis, representing an energetic reaction of the tissue against the toxic action of the parasite. No inflammatory changes of the lymphatic follicles (atrophic or hypertrophic folliculitis) were observed, nor any abscesses with a tendency to perforate, such as are seen in true appendicitis. Microscopically the follicles remained normal, with no indication of leucocyte infiltration, but deep within the mucosa there were signs of more or less hemorrhage. At some points in this tissue there were roundish empty spaces which appeared like the mould of the parasite. The entire picture was such as to suggest that the condition resulting from its infestation might more properly be called oxyuriasis of the appendix than appendicitis from oxyuris. In cases of appendicitis where no emergent conditions exist it would seem advisable that an examination of the feces be made before proceeding to operation, since there are cases in which anthelmintic treatment might accomplish the disappearance of all the symptoms. — *Riforma medica*, September 21, 1931.

Chronic Foci of Infection in the Oral Cavity—H. Passler expresses the view that there is no need of assuming a special peculiarity in the tonsillar tissue by virtue of which it is predisposed to the development of chronic foci of infection. Any such disposition that the tonsil may have is due naturally to its anatomic architecture and to that of its immediate surroundings, not to the nature of the tissue. Not the true tonsillar tissue, but the ramified hollow spaces of the crypts and of the paratonsillar cavities furnish the permanent residence for masses of bacteria. Owing to the narrow and somewhat tortuous passages leading from these spaces toward the free oral cavity, which is particularly well provided with defenses against microorganisms, nearly every inflammatory swelling of the tonsil parenchyma results in a tight closing up of these exits which may remain closed or at any rate become still narrower after the infection has passed its acute stages. The shutting off of the crypts

from the oral cavity and its saprophytic flora deprives the former of the benefit of these natural defenses. In addition the hollow spaces of the recesses of the tonsil offer the optimal bodily temperature for the growth of pathogenic microorganisms, besides furnishing a favorable nutritive material in the secretions of the injured neighboring tissues. Thus it is the location of the tonsillar and paratonsillar cavities that makes them incapable of availing themselves of the nearby defenses, since the carriers of these defenses—that is, the living blood and living tissue cells, are not present in these cavities, to which Passler accordingly gives the name of “dead spaces.” It is in these dead spaces that foci of chronic infection become formed, walled off from the free oral cavity, and hence capable of causing from time to time reactions in the surrounding tissues and the transportation of microorganisms to other parts of the body far removed from the source of infection. Other similar dead spaces are found at the apices of the roots of the teeth and in the openings in the paradentium which become pockets for infection, resulting in alveolar pyorrhea. All these result not only in the fostering of infection but in the resorption of various foreign substances. Not only are toxins present, but we have to deal with proteins and their decomposition products from dead bacteria and tissue elements, with resultant changes in reactivity and with allergic and hyperergic reactions, which probably play an important rôle in the pathogenesis of secondary diseases.—*Munchener medizinische Wochenschrift*, September 25 and October 2, 1931.

Treatment of Sprained Ankles—In dealing with sprained ankles W. E. Tucker lays down as the first rule that all sprains except very mild ones should be examined roentgenologically. His second rule requires rest for all damaged structures. If the sprain is of moderate degree, the ankle should be firmly strapped, and walking allowed if not painful. Massage and radiant heat should be applied over the strapping, and active movements, without producing pain, should be allowed from the beginning. The strapping is removed on the fourth day, if there is absence of pain on passive movement to its full extent. The ankle is then supported by an elastic ankle or crêpe bandage until it feels to the patient completely recovered. Foot exercises should be advised to prevent recurrence and also to guard against a painful flat foot. If the sprain is severe, the patient should be confined to bed for a week, if possible. Firm pressure bandages should be applied over lint soaked in some evaporating lotion (liquor hamamelis 1 in 6, or lead and opium lotion). The next day the ankle is massaged gently, heat is applied, and active movements without producing pain, are encouraged.

This treatment is continued at least once daily. If available, diathermy through the ankle and surging faradism to the muscle will help to absorb deep-seated effusion quicker than any other form of treatment. At the end of a week the patient may be allowed up with the foot supported by strapping, a firm bandage or an elastic bandage. Massage and physiotherapy are continued until full range of active movements is obtained without pain. In severe sprains with fracture the treatment is the same, except that the patient is confined to bed for ten days. If he cannot remain in bed, he is advised not to place the foot on the ground, but to walk with a crutch. The massage and physiotherapy treatment should be continued. For chronic sprained ankle, if it is seen within the first month, massage, movements, and physiotherapy undoubtedly constitute the best treatment, with the ankle supported in the correct position. If seen after the first month, the foot should be manipulated through its full range of movements under an anesthetic in order to break down adhesions, following this with massage and physiotherapy. Where the ankle is continually twisting the best way to strengthen the muscles is by applying surging faradism and carrying out appropriate exercises.—*The Lancet*, October 17, 1931, ccxxi, 5642.

Posthemorrhagic Blindness.—Occasionally, says L. Genet, great loss of blood is followed by disturbances of vision which may even end in blindness due to atrophy of the optic nerve. It is curious to observe that as a rule these effects do not immediately follow the single extensive hemorrhage but are more frequently produced by a series of repeated hemorrhages which leave the subject anemic. The hemorrhages most frequently observed in this connection have been gastroenteric or uterine, whereas traumatic hemorrhages seldom provoke blindness in this way. It is customary for such visual troubles to appear between the 3rd and the 16th day after the hemorrhage, though in some cases they are observed during or immediately after its occurrence; rarely are they seen later than the 21st day. In some 50 per cent of the cases they disappear without sequels, but when optic atrophy supervenes it generally goes on progressively until the sight is definitely lost, and permanent blindness remains. Those lesions which lead to optic atrophy have their seat in the layer of nerve fibers of the retina and in the ganglial cells. While ischemia is the most important cause of these atrophies, it is probable that other causes of a toxic or infectious nature, or phenomena of colloidoclastic shock, enter into the etiology. The unfavorable general condition of the patient, malnutrition and the like, also no doubt plays a rôle. The pathogenesis remains obscure, for these cases are rare, and their severity seems not to bear any definite

relation to the intensity of the hemorrhage. It is possible that an earlier infection of the organism with syphilis or tuberculosis, an alteration of the blood or vessels in individuals affected with lesions of the alimentary canal, or an alcoholic taint may have a predisposing influence. The prognosis is unfavorable, but there is still room for hope of cure after 2 or 3 days of total blindness. The most difficult cases are those where the visual disturbances appear between the 2nd and 10th day, whereas those in which functional troubles are observed within a few hours of the hemorrhage seldom lead to optic atrophy. Treatment consists first of all in hemostasis, but vasoconstrictor substances are strictly contraindicated. When hemorrhage has been controlled, recourse should be had to vasodilator medication and measures directed toward overcoming acute anemia. In the phase of partial atrophy, general hygienic methods have their place, with special reference to ocular hygiene.—*Journal de médecine de Lyon*, October 5, 1931.

A New Treatment for Acute Bursitis.—While treating a patient for boils, who also had symptoms of a mildly inflamed sub-acromial bursa, T. K. Richards administered intramuscular injections of iron-arsenic compounds along with other forms of therapy. After each injection the patient volunteered the information that his bursa felt better. Shortly after this the condition of the bursa became more acute and it was decided to try the iron-arsenic preparations intravenously. After five injections of iron cacodylate, the acute symptoms had disappeared and there was no restriction of the shoulder motions. The results were so striking that the author has tried the treatment in approximately seventy cases of acute bursitis, three of which he describes in detail. In many cases of acute bursitis uncomplicated by a focus of infection elsewhere in the body, there has been an immediate lessening of the acute symptoms within three or four hours following the first injection. The majority of the patients have returned to their normal activities, with complete absence of symptoms and no restriction of motions, from ten to twenty-one days after the first intravenous injection. Iron-arsenite and iron cacodylate were both employed, but as the iron-arsenite was more frequently accompanied by immediate severe reactions, its use was abandoned in favor of the iron cacodylate. The general procedure consisted in giving not more than 3 c.c., or 3/5 of a grain, of iron cacodylate intravenously on the first visit. On the third or fourth day the injection was repeated, using 5 c.c., or 1 grain. This was repeated every third or fourth day until all symptoms had disappeared. The number of doses required to obtain this result varied somewhat. The injection should be made slowly, and great caution should

be used to avoid injecting any of the drug into the tissues about the vein. There is no x-ray evidence which indicates that there is any hastening of the absorption of the lime deposit in the bursa. However, by making motions painless it will prevent the formation of periarticular adhesions and thus avoid distressing complications. —*New England Journal of Medicine*, October 22, 1931, ccv, 17.

The Influence of Sympathetic Nerves on Voluntary Muscles.—Leon Asher, writing in the *Schweizerische medizinische Wochenschrift* of September 5, 1931, states that he and his co-workers have succeeded in showing that under normal conditions impulses coming down the sympathetic nerves have an influence on the efficiency of voluntary muscles. By using frogs without forebrain but otherwise normal, and registering the normal contractions of the extremities, it was demonstrated that on the side where a few days before the sympathetic had been cut, contractions lost their intensity much sooner. When the action currents of the normal side and of the side deprived of its sympathetic stimulation were registered by means of the same preparation, it was observed that after a time the diminution of these currents on the side without the sympathetic appeared more promptly and was more pronounced. The value of these experiments lies in the demonstration that in activity emanating from the central nervous system, impulses reach voluntary muscles not only by way of the cerebrospinal nerves but also by way of the sympathetic. The experiments of these workers clearly demonstrate an influence of the sympathetic on the activity of voluntary muscles when fatigued. Only if Boeke's view that sympathetic nerve fibers enter into the contractile substance itself is correct, is it permissible to conclude that the sympathetic impulses have a direct influence upon the muscle fiber itself. But if on the other hand Hinsey and Wilkinson are right in denying that any sympathetic fibers enter the muscle, the explanation must be sought in another direction. As there remains only the possibility of sympathetic fibers running to the blood-vessels, a test might be made of the idea that sympathetic stimulation produces from the cells of the blood-vessels a substance which acts only upon fatigued muscles. Such a view is supported by the fact that adrenalin acts in this way and that the sympathetic stimulation has rather a long latency. Asher has tested this idea by perfusing the hind limbs of the frog and comparing the action upon the frog's heart of the perfused fluid from periods with and without sympathetic stimulation. In his experiments the effect of the

fluid from the period of sympathetic stimulation was identical with that of adrenalin. Further experiments are in progress to determine whether sympathetic stimulation acts by way of some hormone upon fatigued muscles, or in some other way.

Endocrine Disturbances in Essential Coxa Vara of Adolescence.—A. Beau says that the action of endocrine secretions upon the phenomena of bony growth is indisputable. The glands chiefly concerned appear to be the thyroid, genital, and pituitary, with the thyroid probably taking first place. The thyroid secretion seems indispensable to the life of cartilage. The genital glands, becoming active at puberty, have the opposite effect, causing the multiplication of cartilage first to diminish, then to come to a stop. In castrated animals, the absence of gonadal secretion results in prolonged multiplication of epiphyseal cartilage. But nothing is absolute in endocrinology, and the derangement of a single gland may set up a disturbance of the entire endocrine apparatus. These purely theoretical ideas find startling confirmation in clinical observation. In order of frequency, the clinical pictures most commonly met in coxa vara of adolescence are the adiposogenital syndrome, the hypothyroid syndromes, cretinism, hypophyseal dwarfism, and various pluriglandular syndromes. A large number of authors have pointed out the coincidence of coxa vara with the adiposogenital syndrome. In all the cases published, radiograms confirmed the coxa vara deformation in connection with the typical general habitus of this syndrome. In many it is expressly stated that an application of opotherapy gave excellent results both locally and generally. Besides these frank cases there are *formes frustes*, in which coxa vara is associated with what may be only slight indications of endocrine disturbance, such as acrocyanosis, tachycardia, adiposity, mild goitre, and slight exophthalmia. Only a systematic examination accompanied by the various exploratory tests and pharmacodynamic reactions can give satisfactory information in cases of this kind. It remains to be demonstrated how the cartilage, affected by nutritional disturbances, gives rise to the particular deformity known as coxa vara, but it seems logical to believe that mechanical factors of body static are here at work. The weight of the body, usually greater than normal because of adiposity, falls upon the nucleus of the head of the femur, whose point of union with the neck (the epiphyseal cartilage) is diseased, so that a slipping toward the base of this nucleus can be easily understood.—*Revue française d'Endocrinologie*, June, 1931.

LEGAL

"COURTS AND DOCTORS"

By LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

A scholarly, interesting and instructive work setting forth the legal rights and duties of the physician in the field of the civil and the criminal law is now available. The title of the book is, "Courts and Doctors." The author is Lloyd Paul Stryker of the New York Bar. The book is published by The Macmillan Company of New York and its price is \$2.00.

Mr. Stryker needs no introduction to the members of your Society. During his tenure of office as your general counsel, he merited and enjoyed your respect, confidence and admiration. The publication of this volume has been eagerly awaited by the medical profession of this State. It fills a long-felt want. In the preface to the book written by Dr. Charles Gordon Heyd, President-Elect of the Medical Society of the State of New York, the history leading to the publication of this work is set forth as follows:

"Mr. Stryker was for many years general counsel for the Medical Society of the State of New York, and during that period had personal charge of the legal policy of the Society and the defense of its members who were sued for malpractice. Before resigning as general counsel of the Society, he was requested by its Executive Committee to put in book form the results of his experiences and his researches in the law of this subject. It was felt that his unusual knowledge and experience in this field should be preserved in permanent form, and that a book by him would constitute an authoritative discussion of the legal problems of the medical profession. Mr. Stryker is exceptionally qualified to write this book by reason of his long experience as trial counsel and his handling for many years of medico-legal problems, both in the trial and appellate courts, as well as before committees of the legislature, and he has thus been able to bring together in this volume the material with which his personal contact with doctors and the courts has made him most familiar."

Unlike many books on legal subjects, the present work is not a mere compilation of cases dealing with the subject under consideration. It is a practical guide for the active practitioner. It is written by a man who not only knows the law of malpractice, but who has applied its principles in actual practice in the trial of numerous malpractice cases. This book is the result not only of exhaustive research but of practical experience as well. The author has not confined himself to

merely defining the legal rights and duties that flow from the relation of patient and physician. In Chapter XII entitled, "Suggestions on Avoiding Being Sued," Mr. Stryker gives advice to the medical profession which every practicing physician would do well to read and apply in his individual practice.

As we have already said, "Courts and Doctors" covers both the civil and the criminal law. The book is divided into seven parts, the first six of which have reference to the doctor in his relation to the civil law. The last part deals exclusively with the doctor and the criminal law. Mr. Stryker begins his book with a chapter devoted to the legal definition of the practice of medicine. Here the author defines, analyzes and explains the definition of the practice of medicine as it now exists in the State of New York. From this point he takes up to a chapter headed, "Doctor and Patient—The Nature of the Relationship." Here Mr. Stryker gives the medical profession some sound, sensible and practical advice on the necessity for tact and character in the practice of medicine. On the importance of tact Mr. Stryker in part has this to say:

"I never kept accurate statistics on the subject, but I always felt that not a few of the controversies between doctors and their patients coming to my notice, might have been prevented by a greater display of tact by the physician. Tact has been defined as a 'fine sense of how to avoid giving offense.' It has likewise been described as 'fineness of discernment as to action or conduct.' Others have spoken of it as an 'intuitive sense of what is true, right or proper.' A fine sense of anything presupposes a sense well developed,—an alert and a trained mind. A sense of how to avoid giving offense could only come from a consideration of the rights, the sensibilities, even the prejudices of others. An intuitive sense of what is true, right and proper can spring only from a generous character and sound ethical development."

"Tact is a priceless asset for any professional man, it is indispensable to the physician. The ills, deformities, physical and mental states of people form the subject-matter of his life's work. He encounters all kinds of conditions of men and women, appreciative as well as critical, intelligent as well as ignorant, reasonable as well as unreasonable, fair as well as mean, generous as well as selfish. From the most unpromising of these, he

may fashion warm friendships, or sometimes bitter enmities. How he will fare with his patients (granting, of course, reasonable competency) will largely depend upon his sense of tact or on his lack of it."

The author then takes up the legal duty of the physician to his patient, and the reciprocal duty of the patient to his physician. These chapters contain reference to the leading cases on the subject both here and in other States. The author then discusses under a separate chapter the very interesting and important subject of confidential communications. The statute of New York State relating to this subject-matter is set forth, together with a large number of cases defining and explaining the operation of the statute.

The necessary elements in a malpractice case are clearly and succinctly stated, and the author tells us exactly what the plaintiff must prove in order to make out a case. In this connection there is a very illuminating discussion of the necessity of expert testimony as applied to malpractice cases. The author's conclusions after reviewing the legal authorities are worthy of quotation:

"First, in the overwhelming majority of malpractice cases a plaintiff cannot make out his case without expert testimony. The necessity for it is the rule, the dispensing with it the exception.

"Second, a bad result does not import negligence,—the rule of *res ipsa loquitur* does not apply—and thereby obviate the necessity for expert testimony, except in the instances enumerated in rules four and five.

"Third, in every case in which the point at issue involves a question requiring for its correct solution scientific or expert knowledge, expert testimony must be adduced before a jury can be permitted to consider it. Any question involving in any way the propriety of the treatment however obvious the question may appear to the layman, requires expert testimony for its solution.

"Fourth, there are border line cases, but the mere leaving of a foreign body does not import negligence, so as to dispense with expert testimony. Usually in such case a plaintiff makes out a *prima facie* case by merely establishing the presence of the foreign body. This, however, may be fully met by the defendant through establishing by expert testimony that the retention of the foreign body did not result from the defendant's departure from approved methods. Thus in surgical sponge cases where the surgeon was justified in relying on the nurses' count and had executed a reasonable search himself, in broken needle cases where the proper treatment was used, but it is shown that with the best of care and skill needles break, in x-ray cases where the plaintiff is not shown to be a non-idiosyncratic or where the rays were necessary to combat the disease and could do so only through the destruction of

intermediate tissues,—in these and similar cases if such expert testimony is adduced by the defendant and is not broken down or rebutted by the plaintiff, there is no case for a jury to consider.

"Fifth, where a physician's failure to use due care is so obvious that by no stretch of the imagination could a scientific question of any kind be said to be involved, such for example, as where a surgeon undertaking to remove a tumor from his patient's scalp lets his knife slip and cuts off his patient's ear,—expert testimony is not needed."

We find an excellent chapter which treats of the physician's responsibility for the acts of nurses, internes and other physicians who are working in hospitals. In this chapter Mr Stryker illustrates very clearly, through the reported cases, that the law does progress and that the courts in the making of their decisions take cognizance of existing conditions in the practice of medicine. As Mr Stryker has well said:

"As civilization becomes more complex there is naturally a tendency towards division of labor. In business, in trade and in the profession some men are found adapted to one particular branch of work, others to another. Thus, in medicine there are internists, diagnosticians, dietitians, cardiologists, pediatricians, roentgenologists, otolaryngologists, genito-urinary surgeons, traumatic surgeons, general surgeons, specialists of one kind or another in other parts or functions of the body, as well as general practitioners. Now, the most competent man is usually the one most in demand. Some surgeons go from one operation to another as long as their strength holds out. In any department of endeavor it is an economic waste for one who can do what few others can accomplish, to spend his time in doing what hundreds of others can do as well as he, and thereby preclude himself from doing what the many are incapable of accomplishing. The courts have applied these principles to the surgeon and have held that he is not responsible for the after-care performed by internes or nurses not in his employ, unless he has expressly agreed to undertake that work."

The author very properly calls the attention of the medical profession, under a separate chapter entitled, "Assault—Operations Without Consent," to the fact that (in the language of our Court of Appeals) "Every human being has a right to determine what shall be done with his own body, and a surgeon who performs an operation without his patient's consent commits an assault for which he is liable in damages. This is true except in cases of emergency where the patient is unconscious and where it is necessary to operate before consent can be obtained." A number of adjudicated cases amplifying this principle are cited and discussed.

Several chapters are given over to a discussion

of the Statute of Limitations as applied to malpractice actions. Perhaps the most important case to which reference is made by the author under this heading relates to a case very recently decided by the Court of Appeals in which it was held that the Statute of Limitations on an act of malpractice begins to run in favor of the physician or surgeon from the date of the alleged negligent act rather than from the time of the consequential injury.

From this point Mr. Stryker discusses at great length the general subject of expert testimony. Some of the headings under this topic are: "What Expert Testimony Is"; "What Constitutes an Expert?"; "The Hypothetical Question"; "The Use of Medical Text Books"; and "The Duty of a Physician to Give Expert Testimony." The author points out very clearly, illustrating his point with actual cases in court, the weakness of the rule with respect to so-called experts in this State. Upon this topic Mr. Stryker has this to say:

"The fact that one essaying the role of expert witness need not have special knowledge or experience covering the particular subject about which he is asked to give opinion evidence seems, as we have said, generally to be held. Yet such a rule, in my opinion, is an exceedingly unjust one. It permits a man to criticize and condemn the work of another physician without having sufficient knowledge or experience to enable him to make a just criticism or condemnation. It allows a physician of long years of indefatigable labor and arduous devotion to a specialized field, to be assailed and injured by an incompetent tyro. It is an encouragement to a certain class of lawyers and to the 'professional testifiers' among the medical profession. It permits a plaintiff with an unjust case to supply a necessary link in a chain of proof and thus to make out a *prima facie* case where no real honest *prima facie* case exists. The venal and incompetent expert,—the pseudo expert rather—is the cause and the justification for a large share of the public criticism which of late years has been leveled at expert testimony in general."

The book contains a very practical chapter under the heading, "The Work of Testifying." Here the author lays down twelve rules for the guidance of the medical witness. These rules have been formulated as a result of the author's practical experience in court.

Part VII of the book, embodying Chapters XXIV to XXX, have reference to the doctor and the criminal law. Here the author takes up, among other topics, the subjects of "Assault"; "Abortion"; "Contraception"; "Narcotics"; and "Prescription of Liquor." Attention is called to some statutes which we feel are not well known; for example, the statute in this State which declares that "a physician or surgeon, or person

practicing as such, who, being in a state of intoxication, without a design to effect death, administers a poisonous drug or medicine, or does any other act as a physician or surgeon, to another person, which produces the death of the latter, is guilty of manslaughter in the second degree." This offense is punishable by a term not exceeding fifteen years, or by a fine of not more than one thousand dollars, or by both. Where a physician while intoxicated does any act to another person 'by which the life of the latter is endangered or his health seriously affected,' he is guilty of a misdemeanor punishable by imprisonment in a penitentiary or county jail for not more than one year or by a fine of not more than five hundred dollars." Another instance cited is that of a New York statute which provides that "a physician who knowingly gives a false certificate, or makes a false representation, for the purpose of enabling or assisting a person, to be discharged, excused or exempted from service, as a trial juror in the city and county of New York, or in the county of Kings is guilty of a misdemeanor." Mr. Stryker points out the inconsistency of having this statute apply only to the counties of New York and Kings.

Mr. Stryker concludes his book with a reference to Dr. Oliver Wendell Holmes, and sets forth in detail some of Dr. Holmes' words of wisdom to the medical profession.

The arrangement of the book is excellent. There is a complete alphabetical list of cases cited, and especially to be commended is the mechanical arrangement of the references. This has been done in such a way as not to interfere with an easy reading of the book, and yet the references are full and complete. The work is in all respects accurate. Mr. Stryker has given to the medical profession the adjudicated cases not only in this State but has also included many of the leading cases in every State in the Union.

Not alone the medical profession, but the courts as well, are indebted to Mr. Stryker for this splendid book. It is reasonable to assume that it will assist the courts of this State to a better understanding of the proper principles of law to be applied to actions of malpractice. It can and should be read with interest and profit by every practicing physician. It has a very important place in his library, since there are numerous occasions in his professional life when it will be necessary for him to consult it. As has been truly said by Dr. Charles Gordon Heyd in the preface to the book, "The book should be not only owned, but read by every doctor as a means of informing himself as to his inherent rights and privileges, and the conditions under which he might invite a suit; and finally, for the sane advice whereby a physician may, in a measure, protect and fortify himself against shameless attacks upon his professional conduct, art and skill."

NEWS NOTES

COMMITTEE ON MEDICAL ECONOMICS

The following report of the sub committee on Public Service and Public Health of the Standing Committee on Medical Economics was received by the Committee on December 15 1931 and its publication in the Journal was requested

Your Sub committee on Public Service and Public Health has given some little consideration to the matter assigned to it, and wishes at this time to present the following findings for consideration, debate, and correlation

The Medical Society of the State of New York is an organization of duly licensed doctors of medicine This organization has among other purposes, that of "guarding and fostering the material interests of its members and protecting them against imposition, and enlightening and directing public opinion in regard to the great problems of medicine"

The organization is one, primarily, of individual practitioners, doctors of medicine maintaining a private medical practice Its members, in a very great majority, render service to the public in an individualistic manner They maintain offices and equipment for this purpose at their own expense They offer a service for the prevention of illness the maintenance of health, and the alleviation and cure of disease This service is available to the general public, and is, of course, utilized by the general public, with the understanding that the physician rendering the service is entitled to a reasonable remuneration from the person to whom the service is rendered

To this particular plan of medical service, a plan to which the great majority of medical men are devoting their lives and talents the term "Private practice" has been given It is the oldest plan of medical practice, and is, obviously, thoroughly tested by time It is a plan concerning the worth of which the general medical profession, and the organized medical profession of the State of New York are thoroughly convinced

So convinced are the medical men of the worth and efficacy of the rendering of medical service through private practice and the impossibility or at least the unlikelihood of the appearance of any plan that could take its place in a satisfactory way, that in the past they have not paid sufficient attention to developments both within and without their profession which bid fair to evolve into a plan that will take the place of the private practice of medicine

Such developments are coming from many sources A small minority of the medical

profession itself is apparently dissatisfied with private practice as at present constituted and is advancing plans for its complete change or modification Various social welfare groups are greatly concerned with medical service and medical practice, and its apparent unavailability to a portion of the general public This latter group, in the minds of your sub committee, is greatly confused as to this particular matter Its members show a great tendency to fail to differentiate between cause and effect, they blame, frequently, inadequate medical service for the tragedy of poverty and destitution, instead of blaming, attacking and attempting to remedy the real underlying cause

Your sub-committee feels, however, that the greatest development at the present time, bidding fair to take the place of private practice, is the development, evolution and ever-increasing amplitude of the thing called "Public health"

The term "Public health" and its practice is difficult to define and delimit to the satisfaction of all In the minds and words of its proponents it is becoming increasingly evident that public health includes all medical effort and service, both preventive and curative The medical and quasi-medical care of the child, the guidance of the adolescent the treatment of the unfortunate devotee of Venus the correction of defects, both physical and mental, education and training in dietetics, prevention and treatment of the diseases of middle age and old age—all these, and many other more obvious and appropriate matters, are included according to the more enthusiastic agencies of public health, in the scope of public health

In the minds of your sub committee public health is, and should continue to be, much more rigidly delimited Public health is, in its essence, the promotion by the public at large, through designated agents and agencies of health for the public at large, but not for the individual as an individual Based upon this definition, public health should have but one concern, and that is the protection of the public's environment Such environmental protection has two subdivisions These are (a) sanitation (b) communicable disease control

Sanitation is without argument the task of public health. The control of water and food supplies, to the end that they be clean, wholesome, and free from disease-producing micro-organisms, is a work, which, being for the public at large, should be done by the public at large. It is obviously impossible for an individual to protect his own water supply, or milk supply, forced as he is by law or the exigencies of modern communal life to partake of the common supply. It is obviously impossible for him to protect himself against the bites of disease-bearing insects and the like by destroying their breeding places, when their breeding places are situated on land over which he has no ownership or control.

Likewise, communicable diseases must of necessity be a matter for public concern. The presence of a disease which can be communicated from person to person forces upon the public at large the prevention of such communication. A case of scarlet fever is not an individualistic matter. Its presence, due to its ready communicability through contagion, renders it a threat to the entire public. The suffering of the disease, the probability of personal sequelæ, and the possibility of personal death, are individualistic matters, to be coped with as such; but the element of contagion, the danger of transference of the disease through direct or indirect contact, is a matter for the public to prevent, through the agency of a quarantine by its public health authorities.

These are the prime duties of public health: sanitation and communicable disease control through quarantine. However, due to the development of bacteriological knowledge, to the control of communicable disease through *quarantine* there must be added its control through *immunization*. The protection of an individual against a communicable disease through immunization is an individualistic matter to the person immunized, but it gains also a **public** interest, because the individual so immunized, not being likely to contract the disease, will not communicate it to the public at large. It is greatly to the advantage of the public to immunize its members against smallpox, for example, since quarantine can be imposed only after the recognition of the disease, while contagion may take place in the preliminary period before the disease has frankly manifested itself.

Although the matter of immunization as a function of public health has been debated, one cannot deny the right and even the duty of the public to offer to its members immunologic protection against disease, because by such protection it is protecting itself. Further, it is the right and duty of the public to *compel*

such immunization at times. And also it is the right and duty of the public, in view of the benefit itself derives from the procedure, to provide the immunization at its own expense, and not the expense of the person immunized.

An important part of the above two main functions of public health is public health education. It is right and reasonable that the public should consider it as its duty to inform its members as to the known facts regarding sanitation and communicable diseases, because in so doing it convinces its members of the reasonableness of its rules and demands, and thus achieves cooperation.

In the eyes of your sub-committee these are the functions of public health. As thus delimited, public health is reasonable, and highly essential to the public weal. But public health, as at present practiced, is not thus bound. It is not *public health*, but *private health*, and its practice is encroaching day by day upon the field of private medical practice.

Your sub-committee, in its studies, finds that official health departments, state, county, and local, together with affiliated and unaffiliated, unofficial health organizations, engage in activities far removed from a properly defined public health. Thus, in addition to sanitation and communicable disease control, we find them in unrelated fields, working and continually expanding, with their expansion often at the expense of more intensive work in the two divisions rightly theirs. We find, often, health departments putting great effort into pre-natal care, a matter entirely individualistic (unless we regard the unborn child as the ward of the State) while at the same time very little attention is paid to obvious sanitary lapses in the environment of the women receiving the pre-natal care. It is disturbing to note the time and effort given by health department leaders to the strictly individual problem of the increase of heart disease, with the installation of heart clinics, and the issuing of large amounts of publicity, and find at the same time in the same locality no rigidly conducted fecal examinations of food handlers for the organisms of enteric disease. To put the matter plainly, public health at the present time is taking on new jobs before it has satisfactorily completed the old. It is becoming a jack of all trades, and the master of none.

Your sub-committee lists the following new or impending public health activities, and wishes to point out that none of them deals, to any but the slightest extent, with environment.

1. According to leaders in public health, food, clothing, occupation, sleep, posture, and personnel adjustment are all matters of public health.

2 The entire subject of tuberculosis has been taken over by public health. Diagnosis and treatment, in addition to isolation, etc., are now the duties of health departments.

3 Mental disease, both diagnosis and treatment, together with such general medical and surgical care as is needed, is now the function of the State.

4 Physical defects crippling, and the like, are becoming the task of public health.

5 The care of the pregnant woman and the new-born child is being claimed more and more by public health as its duty.

6 The medical and surgical care of the school child is now a public health matter almost entirely.

7 Tuberculosis clinics supported by public funds, are branching further into the diagnosis and treatment of other forms of respiratory disease.

8 Heart clinics are now a part of some health departments, dealing with the diagnosis and sometimes the treatment of cardiovascular diseases.

The above examples are sufficient to show that public health, no longer content with the

task of the control of environment, a task which to date it has not half completed, is reaching out and obtaining control of the individual.

Your sub committee submits this preliminary study, and begs for more time for its work. In the meantime it makes the tentative suggestion that the Committee on Medical Economics of the Medical Society of the State of New York take it upon itself to watch at all times this increasing control by public health of the individual as opposed to the environment. Such control of the individual as has already been obtained by public health may be difficult to shake loose, but any increase in that control must at all times and in all places be opposed to the last by an enlightened medical profession, alive to the public welfare and its own.

JOSEPH C O'GORMAN,
*Sub Committee on
Public Service and Public Health*

December 15, 1931

COMMITTEE ON PERIODIC HEALTH EXAMINATIONS

Weekly broadcasts on Thursday mornings at 11:30 over the Columbia Chain, under the direction of the Committee on Periodic Health Examinations of the Medical Society of the State of New York were given in January from Washington, under the direction of the Surgeon General of the United States Public Health Service, Hugh S. Cumming, M.D.

The speakers and sponsors were as follows:

January 7th Estella F. Warner, M.D., introduced by Mrs. Hugh S. Cumming, Member, Board of Public Welfare, District of Columbia.

January 14th, Louise Taylor Jones, M.D., introduced by Miss Catherine McCail, National Director of Education of American Association of University Women.

January 21st, Estella F. Warner, M.D., introduced by Mrs. John F. Sippel, National President, Federation of Women's Clubs.

January 28th, Estella F. Warner, M.D., introduced by Miss Belle Sherwin, National League of Women Voters.

The February program is under the direction of Doctors Walter A. Calihan and Marion C. Potter, of Rochester, for Monroe County.

The March broadcast will be under the direction of Doctor Nelson G. Russell, of Buffalo, for Erie County.

C. WARD CRAMPTON, M.D.
*Chairman, Committee on Periodic
Health Examinations*

COMMITTEE ON PHYSICAL THERAPY

The interest and active work in physical therapy in the County Societies has shown gratifying progress during the first half of the current fiscal year. The following Counties have committees on physical therapy: Bronx, Erie, Kings, Montgomery, New York, Niagara, Onondaga, Otsego, Rockland, Steuben, Ulster, Washington.

Lecture courses on physical therapy are being

given under the auspices of the Committee on Public Health and Medical Education and with the cooperation of this committee in the Counties of Onondaga, Bronx and New York, courses in the near future are being planned for the Counties of Sullivan and Rockland.

Meetings with illustrated talks on physical therapy were held or are scheduled to be held in

the counties of Broome, Chenango, Otsego, Rockland, Saratoga, Schoharie and Ulster.

The number of county medical societies in which active interest is taken is thus considerably greater than in previous years. With the excep-

The teaching of physical therapy in medical colleges and post-graduate schools has likewise made satisfactory progress. There is no need in New York State any more for any of the commercialized "courses" on physical therapy given

SURVEY OF PHYSICAL THERAPY INSTRUCTION IN MEDICAL COLLEGES OF NEW YORK STATE—1932

	UNDERGRADUATE TEACHING	GRADUATE TEACHING	SPECIAL
Columbia University College of Physicians & Surgeons	3rd yr. students—8 lectures and demonstrations 4th yr. students — optional clinical work	Under advisement	3 months resident service at Presbyterian Hospital
Cornell University Medical College	Casual clinical instruction; therapeutic courses in medicine and surgery	None	
New York University University & Bellevue Hospital Medical College	None	None	1 yr. course for (non-medical) physical therapists at Hospital Ruptured & Crippled in New York
New York Homeopathic Medical College	3rd yr. students—11 lectures 4th yr. practical course two mornings a week	None	
Long Island College of Medicine	None	None	
New York Post-Graduate Medical School of Columbia	—	Casual instruction in courses of orthopedic and traumatic surgery	
New York Polyclinic Medical School	—	2 months course in theory and practice	2 months service of internes in physical therapy department
Syracuse University College of Medicine	Senior class in second semester, weekly lecture and demonstrations	Physicians admitted to observe clinical work	
Union University Albany Medical College	Casual instruction in general therapeutic courses and in conjunction with general medicine		
University of Buffalo School of Medicine	All undergraduates receive lectures and demonstrations	Subject included in program of Annual Post-Graduate Course	
University of Rochester School of Medicine	Senior Class—3 hrs. a week for 4 weeks (Demonstrations)	Physicians admitted to observe clinical work	

tion of two, all of the larger county societies have organized committees to safeguard the interests of public health and those of the medical profession in regards to physical therapy, as part of the practice of medicine. During the remainder of the fiscal year an effort will be made to stimulate the inactive societies.

by manufacturing concerns or self-appointed "lecturers" with the all-too evident tendency of sales promotion. A tabulation of physical therapy instruction in medical colleges of the State is herewith appended.

RICHARD KOVACS, *Chairman.*
January 15, 1932.

COMMITTEE ON LEGISLATION

To County Society Legislative Chairmen—Enclosed you will find the following bills:

Senate Int. No. 11—Dr. Love; the bill which he carried last year "in relation to mixing babies."

Senate Int. No. 71—Mr. Hastings reintroduced his medicinal liquor bill of last year.

Senate Int. No. 79—Mr. Mastick reintroduced the bill which he had last year, amending the Workmen's Compensation Law in relation to occupational diseases arising out of employment. The justice of this amendment is obvious, but the physicians must remember that many instances are likely to arise in which the establishment of a disease or disabling condition will be exceedingly difficult and on such occasions the entire burden of proof will rest with the physician. An excerpt from a report on the operation of health insurance in England is directly to this point: "Doctors have, no doubt, in the past proceeded on

the assumption that in cases in which there were no definite physical signs, the patient's account of his subjective symptoms might in general be accepted in the absence of any indication to the contrary." Fraudulent claims of the insured have become so evident that the Minister of Health has found it necessary "to remind practitioners that the statutory test of title to these benefits is that the insured person has been rendered incapable of work by some specific disease or bodily or mental disablement, and that strict regard must be had to this criterion in considering all cases coming before them."

Assembly Int. No. 116—Mr. Doyle and the physician for whom he is introducing this bill had a conference with the Legislative Chairman during the summer and the present bill is the outcome of that conference. It seems wise that this amendment should be enacted.

HARRY ARANOW, *Chairman*.

ONEIDA COUNTY

The annual meeting of the Oneida County Medical Society was held on January 12, 1932, in the Hotel Utica, Utica, N. Y.

Dr. T. H. Farrell presented the report of the Committee on Public Relations. It showed that addresses on public health had been given before many organizations which welcomed the interest and advice of physicians.

In the County Hospital there have been treated some patients who should have been cared for by doctors in their home towns. The report described how authorization for such treatment may be obtained, and also the rates.

Dr. W. C. Jensen, Superintendent of the Oneida County Tuberculosis Sanatorium, reported on an investigation by Dr. S. A. Mahady for the detection of incipient tuberculosis among children in Utica who had been living in homes where there were active cases of tuberculosis. Dr. Mahady obtained information from the city records, and the children were tested at Broadacres. Of 347 examined, 227, or 70 per cent, gave positive results. There were 220 x-rayed. In New York Mills, 166 children were found underweight, and 28, or 16 per cent, reacted.

Dr. F. M. Miller, Jr., medical economics committee, reported a tentative fee bill which has been approved by about thirty counties in this state for doctors' services in compensation insurance cases. By this plan an injured person may have his own doctor take care of him and cases can be settled by arbitration rather than by law suit.

Mr. W. B. Edwards, County Welfare Commissioner, appeared before the Society by invita-

tion and explained the working of the system of relief for sickness and for old age.

Dr. H. J. Ball, District State Health Officer and Chairman of the Public Health Committee reported on the diminution of communicable diseases in Oneida County, and stated that four county public health nurses were now at the service of physicians.

The officers elected were: President, Dr. E. M. Griffith; Vice-President, Dr. B. P. Allen; Secretary, Dr. William Hale, Jr.; Treasurer, Dr. H. D. MacFarland; Librarian, Dr. T. Wood Clarke.

Censors—Drs. W. B. Roemer, B. L. Rockwell, R. H. Hutchings, E. E. Porter, M. D. Graham.

Delegates to House of Delegates—Dr. Andrew Sloan; alternate, Dr. H. F. Hubbard.

President Griffith appointed these committees:

Legislative—Drs. G. M. Fisher, H. D. MacFarland, W. B. Roemer, F. M. Miller, Jr.

Public Health—Drs. Halsey J. Ball, H. H. Shaw, A. P. Clark, H. H. Williams, L. H. Eames, Karl Sanford, A. C. Kline.

Milk Commission—Drs. H. H. Shaw, E. E. Powers, A. G. Davies.

Public Relations—Drs. T. H. Farrell, J. L. Golly, A. M. Johnstone, R. D. Helmer, C. R. Bartlett.

Industrial—Dr. Vaughan W. Dutton, C. E. Davis.

Medical Economics—Drs. F. M. Miller, Jr., T. Wood Clarke, H. N. Squier, H. J. Teller, John Gromann.

The retiring president, Dr. Hutchings, read an able and instructive paper on the progress made in this state in psychiatry since 1825, and incidentally he sketched what had been done in this county by this society in 1836 by Dr. Charles B.

Coventry and Dr. John McCall, Utica, in securing an appropriation for the first hospital at Utica a mile and a half west of the city.

WILLIAM HALE, JR., *Secretary*.

KINGS COUNTY

Scientific Program: The scientific program of the stated meeting of the Medical Society of the County of Kings, on Tuesday, December 15, 1931, was as follows:

1. Address: "Neuropsychiatric Problems in Medicine," Lloyd H. Ziegler, M.D., Albany, Professor of Neurology and Psychiatry, Albany Medical College.

2. Address: "Medical and Other Conditions in Soviet Russia," Lewellys F. Barker, M.D., LL.D., F.A.C.P., Baltimore, Emeritus Professor of Medicine, Johns Hopkins University School of Medicine.

Officers: At the stated meeting on Tuesday, December 15, 1931, the following were elected officers for 1932:

For President, William Linder.

President-Elect, John J. Masterson.

Vice-President, J. Sturdivant Read.

Secretary, James Steele.

Associate Secretary, Joseph Raphael.

Treasurer, John L. Bauer.

Associate Treasurer, August L. Harris.

Directing Librarian, Jaques C. Rushmore.

Associate Directing Librarian and Curator, Edwin P. Maynard, Jr.

Trustees for 5 years, Walter D. Ludlum, Frank L. Babbott, Jr., William Browning.

Censors for 2 years, Milton G. Wasch, Henry M. Moses, Irving Gray.

Delegates to the Medical Society of the State of New York for two years 1932-1933, John L. Bauer, John E. Jennings, Joseph Raphael, O. Paul Humpstone, Thomas M. Brennan, Walter D. Ludlum, Harvey B. Matthews, Robert F. Barber, Siegfried Block, Gordon M. Gibson, Benjamin Rabbiner.

Radio: The Council of the Medical Society of the County of Kings instructed the Public Health Committee to establish a sub-committee on Radio Broadcasting, for the County of Kings. This committee is planning fifty-two weekly broadcasts over a Brooklyn station, WBBC, on Mondays, at four fifteen in the afternoon. This committee consists of Dr. Alfred E. Shipley, Dr. Frank D. Jennings, Dr. Alec N. Thomson, Dr. Samuel Zwerling, Dr. William S. Hubbard. The committee has elaborated rules in conformity with the principles of Popular Medical Publicity, printed in the State Journal, Dec. 1, 1931.

These weekly talks began on December 21st, with a talk on Pre-Natal Care of the Child, by Dr. William C. Meagher, and will be continued by other speakers, carrying the child through early adolescence, with emphasis on communicable diseases.

The talk on Dec. 28th will be given by Dr. Joseph C. G. Regan, on Smallpox. That on Jan. 4, 1932, will also be given by Dr. Regan, on Diphtheria.

Libraries: Another rare and interesting work for our collection of incunabula has come to us in a lot of books recently presented. It is a copy of Candidus, [Petrus]. De genitura hominis. It is an undated book, published in Auguste [Augsburg], by Johannem Froschauer. (Hain No. 4320.) There is a notation on the flyleaf that this is the third edition of this curious work and that it was printed between 1496 and 1499.

We have only been able to trace three other copies of this same edition in libraries throughout the world, one in England and two in this country. Only one of these copies is in a medical library. In one instance the date is believed to be 1498 and in another about 1493.

The text is in Latin and the entire book consists of only eleven printed leaves. Nothing can be found relating to the author.

This now makes twenty-six works in our collection of medical books printed during the period of the infancy of printing from about 1450 to 1500.

Electric Light Rates: As a result of conferences with the electric light companies conducted for the Co-ordinating Committee by the Committee on Medical Economics of Kings County, the companies will continue to classify physicians under the residential rate, unless the office from which the physician conducts his professional work is separated from his residence.

This readjustment will, of necessity, take some time. The medical profession is requested to co-operate with the electric light companies in this readjustment.

In case of any misunderstanding, the physician who is a member of the County Medical Society will state his individual case in writing and forward it to the County Medical Society for transmission to the proper electric light company.

Medical Clinics: The medical profession of Brooklyn is cordially invited to attend the regular weekly medical clinics held every Tuesday from 12:00 to 1:00 in the wards of the Kings County Hospital. Abstracts of cases, discussion of diagnosis in difficult cases, and interesting autopsy material, are presented. Here is an opportunity for one hour of clinical medicine in one of our largest city institutions.

Medico-Social Service: The problem of the unmarried mother comes before the Information Service of the County Society from time to time. The Bulletin is informed that one of our members has suggested that a notice of the work being done in this connection should be brought to the attention of the Society through publication.

In the course of a year such organizations as The Church Mission of Help, The Jewish Social Service Bureau and the Catholic Charities of Brooklyn take care of a considerable number of individuals falling under the following classes:

1. The unmarried mother and her baby. 2. The girl needing care to prevent delinquency. 3. The delinquent girl on probation to the Women's Court. 4. The girl committed to Bedford Reformatory for Women who also remains under care during the two-year parole period.

The following types of service are also rendered:

Prenatal and maternity home care for the un-

married mother; physical examination, surgical and medical care; psychiatric examination and treatment. Finding of sympathetic homes for girls and babies; recreational opportunities. Assistance in understanding family relationships, and in making personal adjustments. Expert vocational guidance with training and assistance in securing employment for which the girl is best fitted. Help in the formation and strengthening of her church affiliations.

The Church Mission of Help performs this service for all Protestant girls on Long Island. It is located at 124 DeKalb Avenue—NEvins 8-5863.

The Jewish Social Service Bureau of 285 Schermerhorn Street, Brooklyn—TRiangle 5-5951—renders this type of service to Jewish young women.

The Catholic Charities of Brooklyn (Health Division), at 283 Hicks Street, Brooklyn—MAin 4-3773—cares for young women of the Catholic faith.

SARATOGA COUNTY

The annual meeting of the Saratoga County Medical Society was held in the Y.M.C.A. auditorium, Saratoga Springs, N. Y., on October 31, 1931, with Dr. William H. Ordway, the President, in the Chair.

Dr. MacElroy reported verbally for the Committee on Public Health and Education saying that already an index of nine hundred crippled children had been made.

Dr. MacGovern reported verbally for the Public Relations Committee. It was moved by Dr. King that the Public Relations Committee and the Public Health Committee be combined in order to draw up plans and draft resolutions to be considered by the society before their presentation to the County Board of Supervisors.

Dr. Towne reported verbally for the Milk Supervision Committee.

Drs. Post and Cornthwaite reported activities in the development of the Hyde Franklyn Spring in Ballston Spa to the extent of \$100,000 for commercial purposes.

Dr. T. E. Bullard reported for the By-Law and Fee List Committee and read the report which

had previously been typewritten and placed in the hands of everyone present at the meeting.

Dr. King reported verbally for the Balneological Committee.

Dr. McElroy said that the Welfare Law would reach a large class of patients who are continually in debt to physicians. He read sections of the law stating that it was mandatory for the Board of Supervisors to provide medical care for the indigent sick, and felt that something should be done to get a list of such patients in the county.

The President appointed the following Physiotherapy Committee: Dr. H. L. Loop, Chairman; Drs. G. S. Towne, and G. S. Pesquera.

Dr. Loop moved that the President appoint a committee to draft resolutions to be forwarded to the Board of Regents of the University of the State of New York through Regent Grant C. Madill, M.D., concerning the investigation of the merits of the various cults who are applying for licenses to practise in New York State. This was seconded by Dr. Towne and carried.

Dr. Leon M. Herbert was elected to membership.

HARRY L. LOOP, *Secretary*.

DUTCHESS-PUTNAM

The annual meeting of the Dutchess-Putnam Medical Society was held Wednesday, January 13th, 1932, at the Hudson River State Hospital, Poughkeepsie, N. Y., and was called to order by the Vice-President, Dr. William A. Krieger, at 8:50 P.M.

The following officers were elected for 1932: President, Dr. William A. Krieger, Poughkeepsie, N. Y.; Vice-President, Dr. S. E. Appel, Dover Plains, N. Y.; Secretary-Treasurer, Dr. H. P. Carpenter, Poughkeepsie, N. Y.; Associate Secretary, Dr. E. Gordon MacKenzie, Millbrook.

N. Y.; Delegate (1932-33-34), Dr. William A. Krieger, Poughkeepsie, N. Y.; Alternate Delegate, Dr. J. N. Boyce (1932-33-34), Poughkeepsie, N. Y.; Censors, Dr. A. L. Peckham, Poughkeepsie, N. Y.; Dr. A. W. Thomson, Poughkeepsie, N. Y.; Dr. S. L. Smith, Poughkeepsie, N. Y.; Counselor, G. V. L. Spratt, Poughkeepsie, N. Y.

The reports of the Public Health, Public Relations, and Legislative Committees were held over until the February meeting.

The Secretary and Treasurer's report was read, accepted and ordered placed on file.

Doctor Folsom welcomed the Society and then he presided over the Scientific Program.

SCIENTIFIC PROGRAM

I. Wilson's Disease—A review of literature and report of two cases—Charles E. Niles, M.D.

II. Correction of Physical Defects by Surgical Means as a part of the Treatment of the Mentally Sick—Robert W. Andrews, M.D., F.A.C.S.

The meeting adjourned at 11:00 P.M. for refreshments.

Present: Drs. Sadlier, Sobel, Gordon MacKenzie, Rogers, Grover, Folsom, Kelleher, Stoller, Poucher, Gosse, Wolff, DeNatile, Niles, Malvin, Andrews, West, Borst, C. E. Lane, Tabor, Appel, Rivenburgh, Thomson, Brown, Ross, Davison, Voorhees, Harin, Leonidoff, Mathers, G. E. Lane, Williams, Baier, Deyo, Huddard, Freeman, Breed, Wolfson, Conger, Benson, C. J. McCambridge, Mahoney, LeSoine, W. J. Thompson, Dingman, Richard Boyce, Groom, Peckham, J. N. Boyce, Carpenter, Krieger. 50.

H. P. CARPENTER, *Secretary*.

RENSSELAER COUNTY

A large number of doctors were present at the regular meeting of the Medical Society of the County of Rensselaer, held in the Health Center on January 12th, 1932. President J. B. Burke was in the chair, and Dr. C. J. Handron acted as secretary. The name of Dr. Chester Swett of Pawling Ave. Sanitarium was proposed for membership. Dr. J. H. Flynn presented an enlarged photograph of the late Dr. Herman Gordineer to the society.

Dr. E. F. Connally, past president, presented a paper on "Welch Baccillus Infection" which was discussed by Dr. C. F. Kivlin.

Dr. William H. Park of New York City stated that he believed that the whole world would soon come to use diphtheria toxoid as an immunizing agent for the prevention of diphtheria instead of diphtheria toxin antitoxin.

He also spoke of the use of the Dick test for scarlet fever, and of the use of the anti-streptococcus serum for the treatment of scarlet fever. Lantern slides were shown illustrating by statistical aid the value of each.

He discussed the use of human convalescent serum for the treatment of infantile paralysis and said that he believed that it was of no use unless it was given before the paralysis had set in. Its value exceeds that of horse serum, but is not yet good enough to warrant general use.

Dr. Park's illustrations were made possible by the use of the lantern given to the society a few years ago by Mr. I. L. Kaufmann of Troy.

The meeting adjourned at 10 o'clock for refreshments and a social hour.

WM. B. D. VAN AUKEN, *Reporter*.

THE DAILY PRESS

AN OLD CURE FOR RHEUMATISM

Mr. and Mrs.—

It's Never Known to Fail

From the New York Herald Tribune, January 4, 1932

FIERY FLYING SERPENTS OF THE BIBLE

A report from the meeting of the American Association for the Advancement of Science in New Orleans that Dr. Richard P. Strong, of Harvard Medical School, had solved the problem of the control of filariasis, has led the editor of the New York *Herald-Tribune* of January 6 to comment on the possible identity of that disease with the plague of fiery serpents described in the Bible in the twenty-first chapter of Numbers. The editors think that an actual flying serpent is the more logical explanation of the cause of the plague. The editor comments as follows:

"Isaiah mentions the southland 'whence come the young and the old lion, the viper and the fiery flying serpent.' Herodotus, also referring to Arabia, which probably was Isaiah's 'southland,' tells how he saw 'the backbones and ribs of serpents in such numbers as it is impossible to describe' at the Egyptian end of the desert pass through which these flying reptiles were said to flock to invade Egypt and where they were repulsed each year, the priests declared, by flocks of the sacred ibis. What is still more significant is the Greek traveler's description of the winged serpent as 'shaped like the water snake. Its wings are not feathered but resemble very closely those

of the bat.' Putting aside for the moment the high degree of credibility which modern researches grant to Herodotus when he is describing what he himself had seen, it is remarkable, to say the least, that the Greek describes his serpent wings in almost precisely the terms a modern geologist would use for the only kinds of flying reptiles known to have existed, the long-extinct pterodactyls.

"Modern commentary on these passages can go no farther than Pausanias went eighteen centuries ago, when he merely wondered what Herodotus had seen and whether he was a liar. Certainly the earlier traveler saw something, for it was not his wont to set down hearsay without naming it. Perhaps some dried and shrunken relic of a pterodactyl was among the treasures of the Egyptian priests who were Herodotus's instructors, just as similar fragments of reptiles almost as old are now in modern museums. Or possibly some kind of flying reptile, pterodactyl or other, actually survived until Egyptian times and did fly outward from Arabia at intervals to afflict Isaiah's contemporaries. It would be a matter of no small interest to find the pass where Herodotus says he saw the serpent bones."

MEDICAL LANGUAGE

What newspaper men think of medical terminology is indicated by the following editorial in the New York *Herald Tribune* of January 4.

"The reclassification of the diseases and ailments of the human body according to cause and

organ affected, with a strongly pronounced preference for English nomenclature, undertaken by the National Conference on Nomenclature of Diseases recently held at the New York Academy of Medicine, is a project which can scarcely fail to com-

mend itself alike to medical authorities and the public, whose health is in their keeping. The list, which is to be printed by the United States Public Health Service within the next two months, will constitute an entirely new catalogue of diagnostic titles, according to Dr. H. Burton Logie, executive secretary of the conference, in which 'English terms in good English usage are to be favored.'

"Long shrouded in a complex Latinate jargon, the practice of what has frequently enough been simple therapeutic or surgical technique has for ages assumed all the forbidding aspects of a profound art and mystery. It is probable that in the new list numerous Latin and Greek terms will continue in use in the diagnosis of eye and skin diseases, but here they are, from long-accustomed

usage, familiar, and in most other cases English terms will be preferred. In general a simplicity of language will obtain, and it is hard to believe that such a practice can be anything but reassuringly healthful in its tendencies and result.

"As with the modern psychologists, who, rather than say a person is 'shy,' assert that he is the victim of 'an uncompensated inferiority complex,' so for centuries physicians and surgeons have oppressed the ailing with portentous diagnoses couched in ominous polysyllables. In a time when, as a result of better health education, medicine and its practice are better appreciated and understood by laymen than ever before, a clarifying simplicity of medical terminology is a project which should find wide public favor."

MANUFACTURED WEATHER

It is often said that man has no power over the weather; but in reality he maintains the weather of his home and workshop at the constant balminess of May or September. He controls the temperature and lighting of his rooms, and the movement of the air currents in his house. He has less control over the humidity of the air, although this, too, is being investigated according to the following editorial in the *New York Times* of January fifth.

"The business of conditioning indoor air to make it comfortable and healthful is still comparatively new. Its success in large public halls makes it seem desirable for home use. The manufacture of a cheap unit for small houses is planned by several companies. Optimistic officials see a \$5,000,000,000 market opening up for this new industry.

"The equipment will be designed to filter, wash,

humidify and circulate air through the rooms of a small cottage or bungalow. As an auxiliary to the heating system, it will send air into the room through pipes with outlets under radiators. One unit recently developed takes up only nine square feet of floor space—it is less than four feet long, about two feet wide and four feet high. Control of the system is said to be 'virtually automatic.'

"In hot Summer weather a small refrigeration unit may be added to lower the water temperature for effectively cooling the air. Summer and winter the windows are kept closed, since the system both cleanses and circulates the air.

"With 'push-button' weather on tap at home, a sizzling hot, sultry day will be a fine time for staying in near the family air-refrigerator, just as now a wintry day of snow and sleet is ideal for keeping close to the cozy fireside—though it may be only an electric glow."

PROFITS FROM BEGGING

The *New York Times* of January 14 comments editorially on the experiences of three reporters in London, as follows:

"The common notion that begging is an easy trade receives a heavy blow from the recent experiment of three reporters for *The London Morning Post*. During the holiday season, when hearts and purses are supposed to open freely, they went into business for a day as pavement artists, organ-grinder, and hawker of penny balloons and monkeys on strings.

"Their takings were very small, a total for the three of \$3.20, with a deduction of some 60 cents to be made on the account of the balloon man,

who gave good change for a bad half-crown. The organ-grinder received little appreciation and netted only 10 cents. The pavement artist fared best, taking in \$1.04. But to get that he had to spend \$5 to hire a 'pitch'—the preserve of an experienced street artist—\$1.25 to rent a bedraggled dog as assistant, and 10 cents for biscuits to feed him.

"If the woebegone dog had been exploited with skill, and if receptive markets for hurdy-gurdy music and cheap toys had been found, the experiment might have proved more profitable. For success, even in begging, a man needs training, experience and a natural bent for his profession."

BOOK REVIEWS

CLINICAL DIETETICS: A Text-Book for Physicians, Students and Dietitians. By HARRY GAUSS, M.S., M.D. Octavo of 490 pages, illustrated. St. Louis, The C. V. Mosby Company, 1931. Cloth, \$8.00.

It is not often that a book on dietetics can have attributed to it any element of fascination; interesting it will be always, but because of the great mass of detailed information it must give, it too frequently resolves itself into a compilation of tables, food values, and diets, with sufficient framework of science to support them. But it is decidedly otherwise with this book of Doctor Gauss. He begins with the food of *Pithecanthropus erectus*, the Pre-cooking Period carries the history of man and his food down through the Cooking Period, the Food Culture Period, when man began to raise animals and plants for food, and ends with the Rational Age of dietetics, which he begins at no earlier date than the twentieth century. It is a very telling stroke to pass from the speculations of what must have been the diet of the ape-man of Java to a consideration of the respiration calorimeter, and all of the scientific work which is bound up with that laboratory machine.

And it is equally pleasing to find the face of Doctor Graves looking out from one of the pages of the chapter on fever, he, who wrote as his epitaph, "He Fed Fevers"; or that of Lavoisier, and William Beaumont, who discovered by observation that the stomach would empty itself of boiled pig's feet in one hour while it took five and one-half hours to rid itself of hard-boiled eggs. These bits of the beginnings of the science make easy going of the later discoveries, and provide a background for the modern charts, lists, chemical formulae, etc. These include x-ray pictures illustrating the various disturbances of the gastro-intestinal tract, and photographs of the different types of bodily habitus with the position of the abdominal organs indicated on the surface, all of which the author insists are fundamental in considering a diet for any individual. No chart or table of importance in the subject that has ever been offered is omitted; yet the book reads easily and one is amazed at the number and magic of the author who thus presents an involved and difficult subject, with a simplicity, directness, and ease; gaining much the same effect that books which are written solely for the laity accomplished. It is essentially scientific, comprehensive, scholarly and fine. It is the "compleat" book on dietetics.

L. C. JOHNSON.

Mrs. Dose, The Doctor's Wife. By JOYCE DENNY. 12mo of 154 pages, illustrated. New York, D. Appleton & Company, 1931. Boards, \$1.50.

Here is a book intended to provoke smiles, dedicated to doctors and doctors' wives "with respect and admiration." The author tells us that the characters are all imaginary. This is as it should be because the reader without a profound appreciation of satirical humor of the English variety and a knowledge of English settings might believe the tales and thus add one more volume to the vast amount of slander that has been heaped upon the medical profession—now adding the wives.

One doctor's wife did not smile as she read it, thought it exaggerated, not a parallel to the life of any doctor's wife she knew and objected to the idea that in order to be a successful doctor's wife a girl had to be a snob and a bluff.

Many readers of such a book will enjoy and believe in the ridicule heaped upon doctors and their wives—and not object as did our American friend, wife and defender. The illustrations illustrate uniquely. A. N. T.

GOULD'S MEDICAL DICTIONARY containing the words and phrases generally used in medicine and the allied sciences, with their definition, pronunciation and derivation. By GEORGE M. GOULD, A.M., M.D. Third edition, revised and enlarged, based on recent medical literature. Edited by R. J. E. SCOTT, M.A., B.C.L. Quarto of 1538 pages, illustrated. Philadelphia, P. Blakiston's Son & Company, Inc., 1931. Fabrikoid, Plain, \$7.00; with Thumb Index, \$7.50.

This 1931 edition of Dr. Gould's dictionary contains many new and commendable features which presage its early appearance on the reference shelves of physicians and laboratory workers. It has been recalled that the demand for the second edition of this unusually comprehensive text was so insistent as to exhaust the previous edition five months before the revised text could be completed.

In the present revised edition, four entirely new reference tables have been added, bringing the total up to one hundred and seventy-four. Of great utility will be the most recently published (1929) International Table of the Causes of Death, which is included. As well as hundreds of new words and modernized definitions of old words, there are included, also, three entirely new tables of pathogenic bacteria, metazoa and protozoa, giving both the old and the new classifications.

Those familiar with the previous editions will recall the reference utility of the physician's dosage tables with important incompatibilities, the veterinary dose table, the weights and measures tables, and the diet table indicating the food value of average servings.

Dr. Gould's advocacy of simplified spelling whenever it is authoritative and his system for simplifying pronunciation will be appreciated by all who must labor with scientific terminology.

The reviewer considers the new 1931 text indispensable in every medical scientist's reference equipment. If in a dearth of dictionaries the reviewer could possess but one, that one would be Gould's. FREDERIC DAMRAU.

FRACTURES OF THE JAWS. By ROBERT H. IVY, M.D., D.D.S., and LAWRENCE CURTIS, A.B., M.D. Octavo of 180 pages, illustrated. Philadelphia, Lea & Febiger, 1931. Cloth, \$4.50.

Ivy and Curtis in this book deal with a subject of keen interest to the general surgeon, oral surgeon, and dentist. Heretofore it has been necessary to wade through a mass of ancient methods and long laboratory procedures, which were sure to discourage the reader.

The presentation of the subject matter is logical and clear and well indexed. Commencing with the Anatomical conditions they take us through fractured jaws in general, with an excellent chapter on fractures of the mandible. Here we find the authors relegating the Barton or figure-of-eight type of bandage as a means of immobilizing a fractured mandible to the limbo it should have been assigned to years ago.

The methods described they have found most useful in the treatment of fractures of the mandible are simple and will find ready use in the hands of the general surgeon and dentist.

The chapters on Roentgenographic Technique by Dr. Ennis and Dietary management of fractures of the jaw by Dr. Scogin abound in practical information.

This book fills a long vacant need in Dental literature and certainly should be read by the general surgeon to whose service fractured jaws are ever assigned.

LAWRENCE J. DUNN.

OUR NEIGHBORS

ENFORCEMENT OF MEDICAL LAW IN IOWA

How the Iowa authorities enforced the law against quacks and illegal practitioners is told in the following leading editorial in the Journal of the Iowa State Medical Society for November, 1931.

"Second only to the high quality of professional services rendered their patients by its members, the Iowa State Medical Society has probably made its greatest contribution to the health and welfare of Iowans through close cooperation with the authorities in the effort to curb quackery. Despite the cry of 'persecution' invariably raised by the apprehended quacks, the state society and its members have responded loyally to the need for protecting the public from untrained and irregular practitioners who continually seek to enter the professions of the healing arts.

"Enforcement of the practice acts is in the hands of

- "1. The various county attorneys.
- "2. The Department of Health through its Law Enforcement Division, and
- "3. The attorney general's office.

"These enforcement activities cover each and all of 'certain professions affecting the public health' as governed by Chapter VIII of the Iowa code and include: medicine and surgery, osteopathy, chiropractic, nursing, dentistry, optometry, pharmacy, podiatry and embalming. Enforcement of these laws began in earnest in 1929 with the appointment of a member of the attorney general's staff as special counsel for the Department of Health and the creation of the Law Enforcement Division in the department. The duty of the law enforcement officer, who began work July 1, 1929, is to secure evidence of violation of any and all of the nine practice acts, and so numerous were the complaints and violations that it was necessary to add a second officer this year. The assistant attorney general assists the county attorneys in the preparation of cases and if necessary heads the prosecution.

"Remarkable results have been achieved in the first two years. While divers persons have been stopped from various violations of each of the practice acts, yet the majority have been illegally practicing medicine, because it is the most desirable field and the most difficult to attain. Hence, of approximately 150 persons who have been stopped from illegal practice

in the past two years, nearly 100 were violating the medical practice act. A few of the more interesting practice cases which are typical of the whole group, are given below.

"It has seemed to many laymen, as well as to members of the medical profession, highly inconsistent that a cult which was founded upon opposition to drug therapy and whose schools do not afford such instruction, should be violating the laws of the state by prescribing or prescribing and furnishing medicine, which is by the code forbidden to any but a licensed doctor of medicine. That such is the case as far as numerous osteopaths are concerned is a matter of common knowledge. Considerable interest was therefore attached to three cases recently instituted against osteopaths who were charged with violating the medical practice act. The first was that of Rollo Hook, D. O., of Logan, in Harrison county, retiring member of the board of osteopathic examiners. Last July suit was brought to enjoin him permanently from the practice of medicine; the case was not contested and a permanent injunction was granted. In September cases were brought against two other osteopaths, W. H. McPheeters of Des Moines and E. B. Groves of Waterloo, on the grounds that in using the injection treatment for hemorrhoids and varicose veins they were practicing internal curative medicine as well as prescribing and furnishing. Neither of these cases has come to trial, but there are indications that both of them will be contested.

"Thus far there have been no cases against chiropractors for the practice of medicine, although in one or two instances a call from the enforcement officer who pointed out the limitations of their licenses, resulted in a discontinuance of such practices. Indeed, not only do most chiropractors seem opposed to any departure from the tenets of their cult, but several of these practitioners have themselves requested that a test case be brought to determine whether or not they may use light therapy and electrotherapy under the law.

"With Norman Baker at their head, a considerable number of smooth-talking, plausible gentry have been operating a fairly lucrative racket in Iowa for some time past. Baker having been permanently enjoined by the Supreme Court of Iowa from further operation of his cancer institute, has leased the institu-

¹ Sodium salicylate, 3 grams per diem for six weeks, had given partial relief.

² Sodium salicylate, 4 grams per diem for eight days, had given partial relief.

³ Every symptom relieved except one slightly painful shoulder.

⁴ Preceded by eleven-day interval of sodium salicylate treatment (48 grams in all).

⁵ Occurred during salicylate treatment.

THIS table summarizes twelve cases of acute rheumatic fever treated with full doses of the chemical Tolysin (ethyl ester of paramethylphenylcinchoninic acid). The routine dosage determined upon was 2 gm. every two hours for three doses, followed by 1 gm. every four hours (four or five times a day) though some unimportant variations in dosage and interval were made in a few of the cases.*

These cases evidence some of the advantages of this chemical (Tolysin) over the salicylates, particularly in the relatively large dosages permitted and the rapidity of symptomatic relief.

Tolysin gives the physician greater freedom from the handicap of complications and from the limitations of the salicylates.

Over the past decade it has demonstrated a marked superiority over the salicylates in the treatment of acute and chronic rheumatism and arthritis. Physicians are invited to receive complete chemical and clinical data.

* A. J. M. S., Vol. CLXY, pp. 708-717 (reprint on request).

In prescribing, maximum effectiveness is attained from Tolysin by proper dosage, as follows: 2 or 3 five grain tablets as an initial dose with a glass of water, repeating in such quantities as to produce a total daily dosage of 12 to 20 tablets. After 60 tablets, allow a rest period of several days to one week. For chronic arthritic cases and use in children, suitable reductions may be made. Give water freely with each dose.

The chemical Tolysin is one of a group developed by The Calco Chemical Company, Inc. (unit of American Cyanamid Company) — an acknowledged leader in the construction and production of organic chemical compounds and particularly the ethyl ester of paramethylphenylcinchoninic acid. Published reports of clinical and chemical research of its Pharmaceutical Division are desirable additions to the physician's library. Write:

on, which is now operated under lease by a licensed M.D., but with an apparent decrease the number of patients."

"One afternoon late this summer, a rather distinguished looking gentleman appeared at the door of a Sac City resident whose wife was suffering from a chronic ailment, introduced himself as from Des Moines and explained that the other gentleman, who was out of the car, was Dr. Charles Mayo of Rochester. It seems that 'Dr. Mayo' had heard of the woman's affliction and might be prevailed upon to take the case. The upshot of it was that the two gentlemen left later in the afternoon, with a cashier's check for eight hundred dollars, which the Sac City resident could charge only to experience. Reports that these two gentlemen are continuing to operate in Iowa have come to the State Department of Health and every effort is being made to locate them."

"In Mason City an organization known as the 'International Goiter Institute' had been operating for some time with one or more laymen actively engaged in managing its affairs. This institute has closed its doors without legal action upon the advice of the Law Enforcement Division of the State Department of Health.

"J. I. Class Health Institutes have recently sprung up in several Iowa cities and the one in Cedar Rapids was chosen as a test case with the prospect that it may go to the Supreme Court for final adjudication. A class health institute makes principal use of various kinds of 'fumes,' but is not above electrotherapy, light therapy, and so forth. As these institutes are operated by laymen, they present a very definite legal problem in medical practice.

"It was discovered last year that Iowa was harboring a new cult—naprapathy; in fact, the enforcement officer assigned to the job found that one of them had been practicing in Cedar Rapids for some twenty-five years without any type of license; that he was an officer of the National Naprothatic Association and that a brother practitioner in Burlington was also an officer of the same organization. Injunction suits were started against each in the district courts. The Linn county case resulted in an adverse decision and an appeal has been made to the Supreme Court. The Burlington case is to come to trial in Des Moines county shortly.

"Not only has it been necessary to stop various types of unlicensed practitioners from practicing medicine, but numerous physicians

having licenses to practice medicine have come to the unfavorable attention of the department. In several instances it has been found that men fully qualified to secure licenses, by reciprocity or otherwise, had merely failed to do so; and these defects and oversights have been remedied.

"One case worthy of note is that of M. C. Graham, Des Moines, who was indicted for manslaughter and for practicing osteopathy without a license by the Polk county grand jury October 23 of this year. The indictments were occasioned by the death, from a ruptured appendix, of a nine-year-old girl whom Graham had allegedly been treating by osteopathy. No rule of law has ever been laid down in Iowa as to what responsibility rests with a person (either licensed or unlicensed to practice one of the healing arts) who shows wanton disregard for human life either through ignorance or carelessness and it is hoped a ruling of the Supreme Court may be secured in the above case which will definitely establish what the law expects of all those engaged in one of the healing arts and the duties required under the law.

"A general problem which is common to all of the nine groups included in Chapter VIII

is that of the corporate practice of a profession. At least one important case has already gone to the Iowa Supreme Court, in which it was found that the Bailey Dental Company, being a corporation, could not practice dentistry, regardless of the number of licensed dentists employed and the fact that they only were treating patients. The attorney general has ruled that this decision is applicable to every profession and every type of corporation so that even an incorporated county medical society may not legally enter into a contract with a board of supervisors. The International Goiter Institute, mentioned above, and various other corporations, have recently either dissolved or gone out of business as a result of the Bailey Dental Company decision.

"Iowa also has faith healers. The principal one to have come to the attention of the law enforcement officers was that of Peter Quigley of Decatur county. Quigley has been enjoined by the district court from the practice of medicine and it is interesting to note that his friends and supporters went so far as to have introduced in the last legislature a bill to legalize the practice of faith healing.

"While no question of law enforcement is here involved, yet a discussion of quackery in

BISMUTH SOLUTION

Bi-Na-Gluconate
in Syphilotherapy
produces no Local
Indurations or
Systemic Reactions.

Bi-Na-Gluconate is supplied in Hyposols (ampuls) 12, 25 and 100 to the box.

A brochure is available describing Bi-Na-Gluconate and its role in the treatment of Syphilis. A copy will be sent to physicians on request.

Special one-time offer—for limited period only—25 Hyposols for \$3.00—cash with order.

Unquestionable experimental and clinical data firmly establish Bi-Na-Gluconate in the highest place in syphilotherapy. It is especially useful in tertiary and congenital syphilis and of great potency in interstitial keratitis, syphilis affecting children and in neurosyphilis.

- a—Bi-Na-Gluconate (Bismuth Sodium Gluconate Colloidal) is a clear, non-viscid, alkaline, organic, water and tissue soluble Bismuth solution in true colloidal state. Each 2 cc. represents 0.016 Gm. ($\frac{1}{4}$ grain) of metallic bismuth with 2 per cent alcohol benzyllic as a local anesthetic.
- b—Complete utilization makes small doses effective. It is painless when injected $\frac{1}{2}$ to 2 inches intragluteally. 10 to 15 injections constitute a course and are given weekly or semi-weekly.
- c—Exhibits extremely low toxicity. Minimum lethal dose is 125 to 150 times therapeutic dose. Produces desired therapeutic effect with no evidence of stomatitis, lead line or salivation. Nontoxic to the kidneys avoiding damage to the epithelium of the convoluted tubules and eliminated without causing irritation.
- d—Roentgenographs show complete absorption in 48 hours. Forms no encapsulating nodules to be simultaneously liberated in serious toxic amounts.
- e—Slowly eliminated thus assuring its full therapeutic availability.

(Continued from page 174—Adv. xvi)

Iowa would not be complete without reference to the organized opposition to public health and scientific medicine to be found in many quarters of the state. It is both unfortunate and significant that the Farmers Union in its state meeting should have gone on record as opposed to the county health unit, as well as the cattle testing law. Without discussing the pros and cons of the latter proposition, the adoption of such a resolution is evidence of an illiberal attitude. The Farmers Protective Association, which seems to exist primarily for opposition to the testing of cattle for tuberculosis, has at various places lent itself to anti-pasteurization campaigns and other anti-public health activities. The Peoples' Protective Association has not been heard of so much since Baker's radio station KTNT, was taken off the air, but its sole and avowed purpose was to combat the 'Medical Trust.' The Medical Liberty League, an offspring of the American Liberty League, which was a union of patent medicines and spiritualism, has been fairly active in Iowa during the past two or three years, especially in connection with opposition to county health units, anti-quarantine programs and campaigns against immunization and vaccination.

"While it might seem at first glance that such anti-medical activities were merely propaganda movements which have their inception in the cult theories, yet the immediate effect is to tear down respect for and confidence in medicine and surgery and to prepare a fertile soil in which the quack and faker may flourish."

HARMONY IN IOWA

The recent issues of the Journal of the Iowa State Medical Society have discussed some controversial points in the management of the society affairs, particularly in three respects:

1. Annual dues increased to \$12.00, from \$7.50, the previous rate.
2. The engagement of a managing director of the society.
3. The system of electing officers of the State Society.

The December issue of the Journal contains a "President's page," in which Dr. C. G. Smith, commenting on the increased dues, says:

"Pay your society dues and retain your membership in organized medicine.

"Be honest with yourself. There is not one practicing physician who cannot afford to pay one dollar a month society dues. The criticism that has recently developed is not, in reality, on account of the raise in dues. It has come about because some members have thought that your

(Continued from page 176—Adv. xviii)

monies have not been wisely expended, that some activities were unnecessary, and because of a more or less general feeling that the direction of all affairs was in the hands of a very few.

"The Journal has recently printed a series of editorials telling of the state society activities and expenditures. Also there have appeared resolutions passed by county societies taking exception to the present activities, expenditures, management, and so forth."

An editorial in the January issue of the Journal says:

"The year has been marked by dissension and dissatisfaction among certain members. At least three separate county societies have drawn up and endorsed resolutions unfavorable to the present program of managing society affairs and critical of our managing director. But a greater number of county societies have gone on record approving the policy of the administration and endorsing the managing director. It is unfortunate that any dissension should have developed within our ranks, since our organization is one for scientific development and professional achievement. The machinery of administering towards these ends should remain secondary to the high purpose of our organization and should never be permitted

to develop situations destructive of fraternalism and the nobler aims of our society. Differences have arisen within the component units of our society so that in certain counties factions have developed and fraternity has dissolved. In some sections meetings have been conducted in which but little of a constructive scientific nature has entered into the program. This is deplorable and if continued will defeat one of the highest aims of our organization."

A sample of the commendatory resolutions passed by county societies is that of the Boone-Story Society, in the January Journal, as follows:

"Whereas certain component county societies have seen fit to publicly attack the administration of the State Medical Society's affairs and even impugn the integrity of its officers,

"We, the Boone and Story County Medical Societies, do hereby express our entire confidence in the said officers and approval of their administration.

"Furthermore, we understand that in said administration they have done neither more nor less than carry out the explicit instructions as outlined by the House of Delegates at Marshalltown in 1930.

"Furthermore we feel that due to the exigencies

"Vitamins are the little things in nutrition, the metals are the little things in therapeutics."

For Stubborn Coccogenic Affections

Collosol Manganese (Crookes)

A Stable Preparation Containing Manganese 1-400

Manganese, when injected, increases the capacity of the body to neutralize many endotoxins, the tubercle bacillus, pneumococcus, streptococcus, staphylococcus, etc. (L. E. Walbum). It raises the power of the body to form antibodies (Madsen) and stimulates regeneration of the blood in nutritional anemias (Myers and Beard).

COLLOSOL MANGANESE does not precipitate on addition to blood plasma and therefore gives rise to the minimum of pain, discomfort and untoward reaction when injected intramuscularly. Numerous published reports testify to its value in the treatment of coccogenic affections, particularly furunculosis, boils, acne, etc.

Supplied for injection in boxes of 6 ½ c.c., 1 c.c. and 2 c.c. ampoules

For oral use in 4 oz., 8 oz. and 16 oz. bottles

Full particulars from

CROOKES LABORATORIES, Inc.
145 East 57th Street, New York City

(Continued from page 178—1st 11)

arising from the approaching session of the state legislature, the society needs more funds to carry on its activities and thus we approve the action of the House of Delegates in asking for increased dues.

'While we do not question the right of any component county society to criticize, we view with extreme displeasure the character of attack that has been made on the officers and committees of the State Medical Society.

"Therefore Be It Resolved that we express our satisfaction not only with what has been done but the hope that they may continue with equal zeal and effectiveness in the future."

The editorial writer in the January Journal expresses the following hopeful outlook.

"The various officers of the society have given largely and unstintingly of their time in assisting the component societies to a healthy scientific and organizational growth. They have sown the seeds of fellowship and fraternity and cultivated the field of scientific endeavor. It would be difficult, indeed, to form any adequate estimate of the magnitude of the donation which the officers have made in time and effort so cheerfully given. The wholeheartedness of the response for service so universally met among our officials is indicative of the enthusiasm which has been manifest in every official activity of the society throughout the year."

CHIROPRACTOR CONVICTED IN TEXAS

The October number of the *Texas State Journal of Medicine* contains the following news item:

"The *Plains News* of August 20, advises that 'A jury in Hale county court this afternoon (August 20) returned a verdict of guilty in the case of the State of Texas versus Dr. D. H. Jerrell, chiropractor, of Hale Center charged with unlawful practice of medicine. His punishment was fixed at one minute in jail and a fine of \$500.'"

"The *Plains News* of August 27 advises that 'Petit jury in county court was dismissed late in the week when Dr. J. J. Vandervoort, local chiropractor, filed a motion to quash the jury panel setting forth in his motion that the jury was disqualified, having already tried him on one charge.' The case was continued to the week of August 31 when a jury will be summoned for the trial. County Attorney Royce Oxford stated Dr. Vandervoort had been convicted on one count, receiving a sentence of one minute in jail and a fine of \$500. Dr. D. H. Jerrell, Hale Center chiropractor, had received a similar sentence on trial of his first case, with a hung jury in the second. It was continued also to the week of August 31."

COURTS AND DOCTORS

BY

LLOYD PAUL STRYKER

Formerly General Counsel for the Medical Society of the State of New York

No matter how conscientiously a physician or surgeon may practice his profession, there is always a possibility that some disgruntled patient may bring suit for malpractice.

Just what are your rights on the one hand, or responsibilities on the other before the law? What precautions should you take in the practice of your profession to avoid the possibility of suit?

Follow the advice of your former general counsel based on years of experience in protecting your interests.

RECLAIMING the DRINKER

By

CHARLES B. TOWNS

*Pioneer in Development of
Towns Method of
Treatment for Addictions*

The Alcoholic, being essentially a medical problem physicians will find valuable help in this book which records the observations of Mr. Towns in dealing with alcoholics for over thirty years. RECLAIMING THE DRINKER, includes quotations from noted physiologists, hygienists and laboratory investigators. It discusses various aspects of alcoholic insanity. It reflects a sympathetic and intelligent understanding of the physiological, the psychological and the human problems involved in the rehabilitation of the alcoholic.

CONTENTS

Why Men Drink. When is a Man Drunk?
The Mental Effects of Alcohol
Alcohol As a Deteriorator
What Animal Experimentation Proves
Is Alcohol a Food?
The Truth About Beer
Prevention of Alcoholic Insanity
Reclaiming the Drinker

*To any physician especially interested
in the alcoholic-narcotic problem, a copy
will be sent with the author's compli-
ments*

MEDICAL SCHOLARSHIPS IN KENTUCKY

The January number of the *Kentucky Medical Journal* contains an article by Dr. V. E. Simpson of Louisville, discussing the distribution of physicians in the State and the preparation for supplying doctors in the future, especially in rural districts. One suggestion is that scholarships be provided for medical students. Dr. Simpson says:

"Menifee County has one doctor for every 5,000 inhabitants, that there is but one doctor in that county and that he is 66 years old. Plainly, the citizenry of Menifee County should bestir itself if it really wants one or more additional doctors. What does Menifee County do about a County Judge or a County Attorney or a public school teacher? It does not expect Christian County to send one of its judges or attorneys or teachers over to work in Menifee. Neither may it expect one of Christian County's doctors to 'come over to Macedonia to help' even if Christian County does have one doctor to every 605 inhabitants. But there is material in a number of Menifee County homes from which a good doctor can be made.

"If no boy or girl in that county who is financially able to acquire a medical education wants to study medicine, then the county, with some help from the state, can make it possible for some boy or girl to study medicine who does want such training but is financially unable to obtain it. A suitable committee could select a candidate by competitive examination from a group of applicants possessing preliminary qualifications.

"The successful applicant should agree to return to Menifee County after graduation and practice medicine for a specified number of years; and for his agreement to practice there he is to receive his premed training in the University of Kentucky and his medical training at the University of Louisville Medical School. The cost of his premed education may be borne by the state and the actual cost of his medical education may be borne by the county. The two years spent in premed training at the State University would cost the state \$300.00 per year, a total of \$600.00. The cost of a medical education per year is approximately \$1,200.00. Thus for an outlay of approximately \$4,800.00 by the county it assures itself the service of a young doctor who knows the home people, understands their viewpoint and is in sympathy with their objectives. For the Medical School the writer can say that such a student, having satisfactorily completed his work at the State University, will be admitted to and afforded every facility by the University of Louisville Medical School for graduation."

Dr. Simpson quotes a plan of medical scholarships in Mississippi, as follows:

(Continued on page 181—Adv. xxiii)

(Continued from page 180—Adv. xxi)

"A similar plan is now in operation in the state of Mississippi though there is the expense is met by the Commonwealth Fund and not by the taxpayers of the counties concerned. Provision is made for five free scholarships each year for medical students in Tulane University Medical Department from the State of Mississippi. Recipients of these scholarships must agree to return to Mississippi and practice medicine in a rural community for a period of at least three years. This arrangement means that annually there will be 20 students in the Tulane Medical School from Mississippi on such scholarships. These scholarships are awarded by the Tulane School of Medicine from among the qualified applicants from Mississippi. There were forty such applicants in 1931. The essential difference between the Mississippi plan and the plan above proposed for counties in Kentucky is that the taxpayers of the counties in need of doctors be called upon to help defray the cost of such education, while in Mississippi the state has been fortunate to arrange with the Commonwealth Fund to finance the training and therefore the candidates are selected from the state at large and are not obliged to return to any designated county to practice."

LIAISON COMMITTEE IN TENNESSEE

The December issue of the Journal of the Tennessee State Medical Association contains the proceedings of the House of Delegates in which a report of the Liaison Committee is given. This Committee is like that on Public Relations of the New York State Society. Its appointment and powers have been vague, but now the Committee has found itself, and is functioning actively. The proceedings say:

"In the record of the proceedings of the House of Delegates of the State Medical Association at the meeting held in Nashville in April, 1928, and published in the April number of the State Journal, may be found the following in the report of the Committee on Public Health:

"Your Committee further finds there is no official means of approach between the health agencies of the State and the State Medical Society. The president, vice-presidents, secretary, nor even the councillors have authority to speak for the organized profession, and in view of this condition we would therefore recommend that the House of Delegates create a liaison committee composed of three representative men, one from each grand division of the State, clothed with the authority to counsel with the health agencies and speak with authority for the State Medical Association upon any subject of public health and preven-

tive medicine which alike concern the public health agencies and the profession as a whole, especially policies and practice in the State's endeavor to control contagious and communicable diseases, to the end that there may be maintained a mutual understanding and a cooperation between the two in handling the questions which are getting so much attention from the people as a whole.'

"It was moved that the report be adopted which motion was seconded and carried. Thus the Liaison Committee of the Association came into being.

"Your Committee is of the opinion that an actively functioning Liaison Committee, composed of members with vision and with an understanding of the rapidly changing conditions of the practice of medicine—economic, social and scientific—can be of very great service to the profession as well as to the health agencies of the state. Insofar as the present Committee is concerned, the only matters brought to its attention were those originating in the State Department of Health. Either through apathy, or ignorance of the existence of a Liaison Committee, nothing has been called to the attention of the Committee by the profession at large. Your Committee will offer for your consideration an amendment to the By-Laws which will include the method of appointing this committee, enlarging its membership, determining the length of office of its members and defining its duties.

"Under date of October 6, 1930, the Secretary of the Association notified us of our appointment as members of the Liaison Committee. The personnel of this Committee, together with that of the other Committees, was published in the State Journal in the November, 1930, issue.

"The only matter coming to the attention of the Committee was that of the method of, or standard for, the selection as 'designated physicians' for the care of crippled children. The facts developed were these: At the regular session of the Legislature in 1929, \$25,000.00 was appropriated to the State Department of Institutions for the care of crippled children: Dr. E. L. Bishop, Commissioner of Health, was charged with the duty of selecting proper institutions for hospitalizing these individuals and the appointment of physicians to care for them, as well as to use his field force to seek out the crippled children and have them come at a specified time and at a designated place for examination by the 'designated physician.' The method employed by Dr. Bishop in selecting the 'designated physicians' was to use the latest edition of the directory of the American Medical Association and every physician found

listed in the directory in the state as an Orthopedist was so designated. It developed that two physicians, commonly known and listed as general surgeons (one from East and one from West Tennessee) applied for appointment as 'designated physicians' to care for these crippled children. The Committee ruled that only those who were known as Orthopedic Surgeons should receive an appointment."

MEDICAL FEES IN WYOMING

The Wyoming section of the October number of *Colorado Medicine* contains the following suggestion for the reduction of medical fees:

"Politicians and labor leaders, to hold their jobs, advocate no cut in wages in order to maintain the present high standard of American living. Deep in our hearts we all know this is an erroneous statement. The union brick layer who received \$14.00 per day, a year or five years ago, can live under the present prices for all necessities of life just as well on \$8.00 or \$10.00 per day when he can purchase flour at \$1.25 per fifty

pounds, whereas a short time ago he paid \$3.00 for the same. The same applies to all classes of commodities such as groceries and clothing, and to most other expenses. It is true that some things have not come down in price, but they will have to do so before any permanent prosperity can be universal. Under the above world conditions it seems no more than just that the fees for medical services be cut by thirty-three and one-third per cent.

"Your editor realizes that such a proposition is not and will not be a popular thing to advocate. The wrath of some members of our profession will fall upon his head, but the justice of such a move cannot be denied if we honestly consider economic conditions existing today. That a flat cut of one-third is much better than secret cuts which are at present going on all through the medical profession is self-evident. The idea of a voluntary reduction of all fees by the medical profession may not be pleasing to consider, but we believe such a move is the only way to meet conditions of today. It seems more fair for all to reduce our prices than to cut them secretly behind each others' backs.

The "Pomeroy" Supporting Corset

A good corset, properly made and fitted, not only gives needed support to the vital organs, but moulds the figure to correct and graceful lines.

The Pomeroy is ideal for this purpose, for it is so designed that the uplift is given by the corset itself with no need for additional belt or other contrivances. The intersecting laces give an extra upward and backward lift which further helps the muscles of the abdomen to give the necessary support.

COUNTY SOCIETY IN DISEASE PREVENTION IN IOWA

The January number of the Journal of Iowa State Medical Society contains the following description of the work of the Clay County Medical Society in disease prevention:

"The Clay County Medical Society has become officially interested in the promotion of the health in Clay county, supporting a compulsory campaign for the immunization of school children against diphtheria and smallpox. A like attitude of sponsorship has been assumed by other county societies with eminently satisfactory results.

"Attention is directed to the Clay County Society's action, since we believe that this establishes a satisfactory form for the conduct of such a project. We are glad, indeed, to add our word of endorsement to the official action of the Clay County Medical Society and other medical societies now sponsoring this work in health promotion, believing as we do that the comparatively large number of cases of diphtheria and smallpox in a state as enlightened as Iowa is disgraceful.

"The text of the resolutions adopted by the Clay County Society is as follows:

"At the annual meeting of the Clay County Medical Society a resolution was adopted recognizing the need for closer cooperation between the reputable medical profession and the boards of education and the school directors of Clay County in matters pertaining to the health and welfare of those who attend the public schools and authorizing the appointment, by the president, of a committee of six who were instructed to arrange for meetings with the county superintendent of schools, boards of education and school directors of the county, and to discuss with them matters of common interest and report back the results of their conferences at a special meeting of the society for such action as the society may deem proper.

"Your committee recommends:

"1. A county-wide campaign urging that protective treatments against diphtheria and smallpox be administered to all children between the ages of six months and sixteen years.

"2. That parents or guardians of children be fully advised of the desirability and safety of such preventive treatment by their family physicians and by the distribution of literature prepared by the State Board of Health.

"3. That public school teachers, parent-teachers associations, women's clubs, welfare associations, American Legion auxiliaries, ministers, the press

(Continued on page 185—Adv. xxvii)

(Continued from page 184—Ad. cont.)

and all others informed and interested be hereby asked to cooperate with the medical profession in disseminating knowledge that smallpox and diphtheria are preventable diseases

"4 That the immunization be given at the office of the family physician at home or school as seems most desirable and practical to parents and physicians and on dates agreeable to both, between January 10th and a date yet to be determined

"5 Your committee expresses its firm belief that with proper cooperation, all pre-school and school children of City county can be fully protected against diphtheria and smallpox by September 1, 1932"

WOMAN'S AUXILIARY IN COLORADO

The editors of *Colorado Medicine* writing in the November issue, make the following appeal to carry the Journal home to other wives

"It is a frequent comment among the members of our Woman's Auxiliary that they 'never see a *Colorado Medicine*'. Some of the members of this Society may not have noticed that this journal carries a section for the physicians' wives. In it are to be found articles upon national as well as local Auxiliary affairs. They are worthy of the attention

of the doctors—and most certainly of their wives

"We are depending upon the support of the wives of the physicians throughout the country to augment our efforts in educating the public in preventive medicine, the health examination and the proper direction of health legislation. They are capable of inspiring confidence where we may fail, they may convey messages to lay organizations which our ethics and humility, unfortunately, preclude. It is for our profession that they have organized and are working. Their value to our cause is unlimited, it will be largely in proportion to the aid and encouragement they receive at the hands of their physician husbands. It is known that a number of physicians are unsympathetic with the Auxiliary and its work. May they allow themselves to recognize the potentialities of this organization and endeavor better to inform themselves of its capabilities

It is hoped that each issue of *Colorado Medicine* will be placed in the hands of the wives of our Society members before each month has passed. There is material in the Auxiliary's section which will be of interest, other sections will further enhance their understanding of the work of the profession"

PARKE, DAVIS & CO.

The following Parke-Davis campaign, started with the January 9th issue, page 69, of the *Saturday Evening Post*.

* * * * *

In these days when many advertisers are trading on the prestige of the medical profession in order to sell their wares, the advertising being done by Parke, Davis & Company in lay journals comes as a welcome relief.

Their intent unmistakably is to direct the public to the door of the regular practicing physician rather than to the

The Westport Sanitarium WESTPORT, CONN.

An incorporated and licensed institution.
FOR NERVOUS and MENTAL DISEASES
ELBERT M. SOMERS, M.D., *Physician in Charge*. Located in an attractive private park on the Boston Post Road. Modern equipment. Adequate personnel and classification.

door of the quack or charlatan. This is a most commendable effort.

Ethics forbid the profession to "speak its piece" in public but a friend of the profession can talk out in meeting and that is precisely what Parke, Davis & Company is doing.

It is seldom indeed that an advertiser has taken up the cudgels so directly, or has taken the medical profession's publicity problem under its wing in such an unselfish way. The unselfishness can be gauged by the fact that the advertisements are devoted wholly to the "see your doctor" theme, and contain no reference to their sponsor other than a modest signature.

Medical men who writhe at certain food, drug and proprietary advertisements will, we think, be interested in following the Parke-Davis campaign. See page viii.—*Adv.*

A MODERN PROBLEM

Is it an overstatement to say that one of the most important problems of modern medicine is the study of the prevalence and treatment of acidosis (hypoalkalinity) and hyperacidity?

Though not classed as diseases in themselves, they constitute serious symptoms which complicate a large percentage of the diseases encountered in everyday practice.

Hence the reason for the frequent references in current literature to the importance of restoring the normal pH—a chemical symbol used to express the hydrogen ion concentration as found, for instance, in the blood and body fluids.

Under normal conditions of health, diet and metabolism, Nature tends to preserve an acid-base balance in the body.

Where poisonous products of incomplete metabolism, such as acetone bodies,

oxybutyric acid, etc., accumulate in the system, or, where the demands upon the alkali reserve are excessive, a state of acidosis exists which undermines the resistance of the patient.

Acidosis is associated with the following well known conditions—diabetes, toxemias and vomiting of pregnancy, diarrheas of children, cyclic vomiting, dermatoses, rheumatism, infective fevers (influenza, pneumonia and the common cold), nephritis, alcoholism, shock, burns, etc. Therefore an important phase of treatment should include the building up of the alkali reserve.

The prevalence of the symptom of gastric hyperacidity is too well known to be reemphasized. It leads to indigestion of the type so often described as a sour stomach, with eructations and heartburn, and is believed to lead to gastric ulcer and other far-reaching complications.

There are strong objections to the administration of massive doses of soda or other single alkalies in acidosis or hyperacidity because alkalization and not neutralization should be the objective.

When single alkalis are used, the therapeutic dosage has to be constantly increased and there is a danger of setting up an alkalosis, with tetany.

More rational and safe is complete alkalization by the use of a balanced formula which seeks to combat acidosis and hyperacidity by building up the alkali reserve.

Such a formula as BiSoDol, which presents in suitable and definite proportion the bases, Sodium and Magnesium, together with adjuvants in the form of Bismuth Subnitrate, Carica Papaya, Malt Diastase and Mentha Piperita is ideal for this purpose for it tends to reestablish the normal alkalinity of the body without danger of systemic disturbance.

That is why it is endorsed in all forms of acidosis and hyperacidity.

BiSoDol is being ethically introduced to the profession. It is carried in stock by all pharmacists. It is palatable and easy to take. The usual dose is 1 teaspoonful in water after meals. See page ix.—*Adv.*

A FEW PROBLEMS OF THE MODERN DOCTOR

By EDWARD H. CARY, M.D., DALLAS, TEXAS

An address by the President-elect of the American Medical Association before the Kings County Medical Society, at Brooklyn, N. Y., October 20, 1931.

I COME to you with the deepest appreciation of the courtesy shown the President-Elect of the American Medical Association, your humble servant, who has the distinction of having been selected by you to this office.

I consider it my duty and privilege in the next two years to carry the fine sentiment of friendship of the headquarters to the rank and file of the membership of the American Medical Association.

When invited to speak to you, the choice of subject was left to me: First, I thought of presenting a scientific paper—then I realized that I could not select a topic in my field which could possibly interest this large, and may I say, varied group.

So I hope, for a time, you will turn from the distinctly scientific aspect of medicine.

I, of course, recognize the appeal one can always make to an audience when the ideals of a great profession are placed in review, glorifying both the men who have always espoused them, and the traditions and virtues dear to us all.

I realize that the term "Materialist" may be attached to the name of anyone who discusses the practical phases of professional life. On my own behalf, may I be permitted to offer the record of the past thirty years of devotion to the furtherance of scientific truths and ideals.

When this great organization of ours, the American Medical Association, was democratized, and each state could through duly elected delegates, express the will of the units which make up the whole, the machinery was at hand to develop on this continent the ideals of the noblest of all professions.

Medical education was at a low ebb, so educational improvement became the great motif that ran through years of constructive planning until our standards and practices equal and in many instances, surpass those of other enlightened countries.

From within the Medical Profession came sup-

pression of the evil of widespread commercialized medical colleges, of which many were bad, although it may be said that some of them were good on account of the devotion of their great clinical teachers. We freely admit that this educational uplift was aided through widespread publicity by the Carnegie Foundation. We, as a profession, at that time, commanded no such avenues of publicity.

It was a reform engineered and made effective by the medical profession encouraged by enlightened public opinion.

There were many great doctors, particularly famous surgeons, in spite of the low standards.

Since our medical schools have reached the requirements set by our Council on Medical Education, the graduates are more uniformly equipped to meet the demands upon them in the practice of medicine.

There has grown to be a widespread conviction that medical men are now rather uniformly taught the medical sciences and have similar clinical experiences.

Personality, keen mental perception, philosophical attitude, interest in patient, and that so-called rare quality, known as "horse-sense"—these and other human values are not necessarily created in the medical school.

There will always be the normal human difference. Yet I must call your attention to the fact that the executive officers of every class "A" medical school now have the privilege of choosing from a large group, the men who are to make up the freshman class, and since migration of students is not encouraged, those who weather the storm, and see the rainbow through the Sophomore year, stick. Their quality too is established under longer surveillance.

I also call your attention to the fact that students are sought routinely and naturally among the applicants, for their educational and moral values, without particular thought or interest in the material side of their professional career.

It all in time, tends to produce in practice, a levelling of talents at work, with returns fairly equalized.

The individual hundred thousand income, these educated young men have heard about, is rapidly disappearing—so is the seven hundred and fifty dollar yearly stipend. There is now an approximate monetary level confronting the modern educated physician, although this is influenced by ability, industry and personality.

The Science of Medicine is, in spite of this general improvement of its devotees, always ahead of the Art of Medicine, an excellent reason for the existence of this great organization of ours, which through your membership provides the means and facilities for carrying into the office and home, through its publications, invaluable supplemental information.

There is also, through our associational contacts, an assimilation of proven facts, and further trial of reasonable clinical conclusions which are heard and later utilized in a professional way. All of which emphasizes the Art of Medicine.

The education of physicians, the process of keeping them educated, is in a way "Big Business," and however objectionable this term once seemed to us, we are now able in our profession to perceive material values and remain idealists—as the successors to the Victorian Period can mention the leg of one's body without offense to the proprieties.

Of course, the danger to our profession is that universal danger, slight though it may be, when repression is removed, the unmoral rebound disgustingly.

I have sometimes suspected that the older practitioners whose virtues have been recounted in song and phrase (God Bless Them), realized their deficiencies, and were governed accordingly. Tradition too played a part, and these fine men often made no financial demands, they simply accepted what came. This custom involved even those who gave tremendously of their knowledge and skill. Even unto this day, people in many places are trying to follow the old custom—the dear old custom—of commanding their doctor with the thought that some day they would get another, if they were disappointed in the utter altruism of this splendid servant of the people.

This old custom, likely Spanish as well as American, has lost favor with that influx into the profession of the newly and more expensively educated men. They seem to feel that they have something for sale which has required time, money and labor to acquire. They too, want to provide for their families. Have they changed their code? Have they ceased to want to care for the indigent? I can say decidedly "NO." But it is fair to state that the profession is beginning to see in the *public*, a joint partner in altruism. Therefore we should insist that for the conserva-

tion of the doctor's and the patient's time, and in the interest of the best scientific service, all inclusive conveniences should be more uniformly provided for the treatment of the sick, whether in city or hamlet.

With this as a working basis, the profession will further insist upon a line of demarcation. On one side voluntary charity, and on the other, a fee commensurate with service performed and the ability of the patient to pay.

As to charity, the members of our profession consider it a great privilege to care for the worthy poor. They properly ask for a correct environment with modern facilities for the conservation of their valuable time.

In Iowa there are fifteen County Medical Societies, handling on a general contract basis, the sick poor of the county. This plan has been in operation over a period varying from one to twenty-seven years. Professional and public opinion now justify the assumption of this obligation by the public, the medical men being paid for the care of all indigents.

Again, we should become joint partners of the Public for the relief of the so-called badly treated and outraged Middle Class, whose interest has filled so many Journals. They must be considered. This Middle Class is made up of persons with varied resources. They want the best medical service at reduced cost. They have many obligations, likely interesting families; they are quite respectable in the community. Unfortunately their income is often not equal to all the demands; then comes illness, and the danger of being submerged financially, if any unusual hospitalization or surgical procedure is required.

Certainly there should be no difference in the quality of diagnosis to anyone—poor, middle class or rich. We recognize that the greater percentage of simple illnesses terminate favorably, which is an aid to the irregular doctor. This offers an equal opportunity for praise, regardless of the merit of the diagnosis.

We, for the moment, are not interested in these numerous incidental ailments. But if we, the better educated physicians, see that the diseases of the really sick are correctly diagnosed; that we accurately interpret the illnesses of the ambulatory, yet potentially sick, and that we make a minimum number of mistakes in our interpretation of disease, then that vast number of those not so sick, will more likely remain in the hands of the regular physician. Hence, it is all-important that we plan to provide for this numerous middle class.

An intelligent self interest on our part suggests that we see that it is done. One of the reasons why it is not done is that many persons unable to pay very much seek cheap medical advice. In the long run, they find the cheap advice the most expensive; but that does not lessen the responsibility

of the able doctors of the community. We should so develop the interest of the membership of the County Societies that the efficiency of the profession is made available for diagnosis regardless of class. The time is probably at hand when organized medical units of the A.M.A. should actively participate in the social service programs of our communities. In fact, we should lead the way.

This cooperation of the profession should contemplate that the laboratory and hospital facilities in County and City Hospitals offer part pay opportunities provided by the public, on a reduced basis for the benefit of that part of the public which is in distress, and for the particular benefit of the people whose budget justifies this cooperative service and whose self-respect makes them abhor charity.

The County Society must be the place where the members can determine for themselves the wisdom of more frequently combining their knowledge for the benefit of all classes, whether rich or poor, without having to do so in free dispensaries. These members can develop a plan; they can be more accurate, they can utilize private laboratories wherever they exist, if the laboratory men are willing to cooperate with the profession in this diagnostic work.

If for any reason this arrangement can NOT be made, then the public should supply such facilities.

The County Society can well afford to give thought to any method which encourages individuals to honestly try to do their part.

Patients in large cities who go to hospitals or dispensaries for charity should be registered so that medical shopping or duplication of effort of all kinds will be prevented. The need for charity should be established.

To advert to the modern medical man—he should know his limitations and be honest enough to admit it. In doing so, he must learn the art of cooperation, and the value of consultations with his fellow practitioners. Cooperation is essential and more enduring where the professional contacts are established without actual partnership and where the frailties of human nature are not strained. Self interest binds one to the patient who remains in hand—but intelligent cooperative consultation as may be needed, holds the patient on account of actual service rendered.

Now it is quite evident that right here, individualism in the practice of medicine falls down. Let us assume that cooperation is largely needed in diagnosis. Since a correct diagnosis is most important, then every doctor should wisely use the best men for that purpose. To do this at the home of the patient seems impractical and too expensive, for it takes more time to make the necessary examination. So the patient whose condition requires a careful analysis must be where the

physicians can easily cooperate, whether this be at a general hospital, or the place provided within the building where the doctors have their offices and where they often jointly own expensive equipment. Here conservation of time and use of laboratory facilities, x-ray etc., make it possible for an early conclusion to be reached at a minimum expenditure. This can be in one fee, consistent with the ability of the patient to pay—the patient to remain in the hands of his individual physician.

It is easy for us to understand that the most expensive medical service that can be rendered to any man or woman is an incorrect diagnosis. Inasmuch as a certain percentage of every man's practice requires the most careful analysis to determine the cause of trouble, then we must stimulate this methodical, cooperative effort on the part of the profession to see to it that patients arr thoroughly studied, and that the method of doing so is to the mutual advantage of the consultants. The patients, yes even the people at large, should know that the fee for such services will not be burdensome.

I am discussing the present day doctor, well educated, who has remained an individualist, for out of the 140,000, there are less than two per cent practicing group medicine.

Correct medical service then, is based upon correct diagnosis. If this were accomplished there would be less complaint and fewer reasons for support of the irregulars. Every County Society, regardless of size, should consider this relation of the profession to its clientele.

Billings has said that "A painstaking practitioner is able, in a great majority of cases, to make an accurate diagnosis without expensive equipment." The plea is made to stimulate more individual effort, to discourage leaning upon laboratories and hospitals, as well as the over-use of specialists. This is fine to preach to timid practitioners, if there be any who have no opinion—and who await laboratory findings to formulate one—but is it not more likely from your own observation that doctors err on the other side, taking the path of least resistance, often jumping to conclusions, or delaying a complete study? FOR THIS DOCTOR is without a plan of cooperation which to him seems practical. The patient is treated expectantly as long as he remains sufficiently impressed, and is correspondingly in his care.

I am suggesting to the members of the profession that they sensibly supply to each other the missing link of knowledge, so worked out, that it is in no way harmful to practitioners, nor too expensive to their patients, and which is in the long run, to the interest of the medical profession as a whole. The term "Practitioner" should suggest to you the medical man best equipped and needed in a given case.

A former President of the A.M.A. advocated that the County Medical Society should organize to conduct a group clinic. His argument was based upon the fundamental grounds that the practice of medicine is a natural monopoly and that if we do not supply to the people competent medical service at a cost within their means, the State will eventually do so. Not differing with Dr. Harris as to the fundamental obligation of the profession, I have always thought that the County Medical Societies, as such, would be unable to proceed successfully along the lines suggested regarding group clinics.

I claim that doctors as individuals, need to combine their talents as needed, to meet conditions as presented. In smaller counties — the County-City Hospital should be the environment for developing medical diagnostic and even curative work—larger cities offer more numerous foci of professional activities—the public and private hospitals are being used, but not routinely as they should be.

Then there have been numerous medical buildings in the larger cities, placed at the service of the profession, where the greatest opportunity is now presented to develop this cooperative spirit of helpfulness toward a correct diagnosis. Help is not always needed . . . it may only be necessary to call one or two more highly trained men in other specialties, the patient always remaining in the hands of his doctor. The so-called high cost of medical service will disappear when we more or less universally adopt cooperative methods, which I could easily explain.

To pursue this thought of efficiency, we are often confronted with embarrassing expenditures, due to unwise counsel at a time when sentiment is regnant.

The modern doctor is confronted with a unique psychology which he unwittingly helped to create.

While I yield to no one in my admiration for the many marvelous women who have gone into the great profession of nursing, it is true that in hospitals and homes, but largely in hospitals, that the man who can often least afford it, is employing special nurses. There has been an over emphasis in what might happen if the patient were without such constant care. There has certainly been an over emphasis upon the social importance of having one's wife as well cared for as the "Joneses."

It would seem that the medical profession could very well afford to hand to the patient who contemplates hospitalization a frank statement containing valuable information as to the important things needed while in the hospital. This card could carry suggestions which would practically eliminate that combination of circumstances surrounding patients in hospitals which creates a feeling on the part of the patient and his family, that special care is imperative. The doctor

should be the sole judge as to when this frequently necessary expense is needed.

In the same way, medical men should be wise enough to know when to use laboratories of all kinds. While I do not in any sense decry their value, that which is not necessary often becomes a very great burden.

What I am trying to say is, that within the profession we must practice discretion in the methods we pursue; we must see to it that our patients are protected from unnecessary expense and have them satisfied, if it is within our power to do so. I am sure you realize that the rich appreciate a considerate attitude on our part, and gladly pay when this is apparent.

Another problem of the modern doctor — **GROUP HOSPITALIZATION** is being utilized in many hospitals throughout the country. When properly organized and safeguarded, it is not a menace to the profession. Groups are chosen on an actuarial basis, both as to the cost to the individuals and numbers of persons sought for hospitalization. Baylor limits the number of members to less than five thousand, spread in all groups to make the law of averages safely apply.

Hospital service is all that is sold. The medical staff is in no way involved. Patients belonging to groups have full liberty of choice as to the physician treating them in the hospital. They must meet **ONE** requirement, and that is that the doctor be a member of the County Medical Society.

Long time commitments to a fixed rate are avoided. One of the best by-products is, that coming to the hospital with the bill already provided for, educates patients to be "hospital-minded." The hospital expense is not an item to embarrass the doctor in collecting his fee.

For lack of time I will not go further into detail. As group hospitalization is conducted at Baylor, it is to the interest of both the patient and the doctor. The hospital has kept more beds busy with the same overhead.

On the other hand, there are hospitals utilizing the group hospitalization idea to the detriment of the profession as a whole. In many cities such service includes, first; medical, surgical, and hospital care; second; dental service, third; home medical attention.

This proffered service is the basis of many attempts on the part of hospitals, enterprising lay-managed organizations and small groups in the medical profession to organize and control medical practice.

Banks and other enterprises have been solicited, and this has led to definite resistance on the part of the general profession. The County Society can control this situation.

The present economic status is an incentive for the members of our profession to lose sight of the common good when working in groups, the ten-

dency is to take advantage of any opportunity to enlarge their service.

While the Judicial Council of the A.M.A. has had various kinds of contract practice presented to it for a ruling, it realizes the difficulties in so defining contract practice that controversy can be avoided among medical men, who otherwise are perfectly ethical in their relation to the profession and public.

The term "contract practice" as applied to medicine may mean the carrying out of an agreement under many circumstances necessary, and consequently, ethical.

"It formulates, however, definite conditions which absolutely establish a contract as being unfair or unethical. Certainly when compensation received is inadequate as based on the usual fees paid for the same kind of service by the same class of people in the community, when the compensation is so low as to make it impossible to render competent service; when there is underbidding by physicians in order to secure the contract; and when a reasonable degree of free choice of the physician is denied those cared for; contract practice is unfair, unscientific and harmful both to the public and to the medical profession."

If the members of the profession do not hold firmly during this depression, we may expect to see less harmony and more withdrawals from our organization, because of the discord which will be engendered.

County Societies everywhere should watch such tendencies and they should immediately institute proceedings to stop the practices which in the long run, lead to inefficient medical service as well as chaotic conditions in our profession.

State medicine is not far around the corner when people find that doctors hold themselves so cheaply.

Another problem of the modern doctor: To the next Congress of the United States, we should turn our attention, for another pressing issue which confronts the profession is the paternalistic demand upon the State and upon the national government.

This will have little effect as it relates to us if we have wisely used our knowledge and considerably conducted our economic relations with the people.

You will find increasing interest in the Shoulders' Resolution introduced in and passed by the House of Delegates of the A.M.A. at the Philadelphia meeting last June.

This is a constructive effort to spread the benefits of Federal Aid to the Veterans of the World War with non-service connected disabilities. This Resolution petitions the Congress of the United States and the American Legion to abandon the policy of rendering hospital and medical benefits to the Veterans of the World War with non-serv-

ice-connected disabilities, and substitute therefor a plan of disability insurance which provides cash payments during the period of total disability with liberal hospital benefit to cover expenses for a veteran during period of hospitalization for any disability.

If the government pursues its present policy it is estimated that there will be an expenditure of two hundred and twenty-nine million dollars per year for the cost of two items alone, besides others contemplated, many of large import.

These two items are hospital maintenance and professional staff. To contrast the far reaching suggested insurance benefits to the non-service disabled, their hospital expense and family protection would be only ninety-two millions per year at its height. With this arrangement the medical profession will be sought for its service as now, the patient using the home physician.

Our profession, and the hospitals of the land, are vitally interested in preserving their relations with this large group of citizens who should remain independent and free to choose their own physicians and hospitals.

Though it is true there would be temporary employment for staff officers where government hospitals were built, the tendency to state medicine would be greatly encouraged, and react destructively on the present system of individualism in the practice of medicine.

To quote Shoulders, "This insurance plan of benefits to veterans is offered in the interest of all; it is in the interest of veterans primarily; it is in the interest of equality of benefits between veterans; it is in the interest of economy in governmental expenditures; it is in the interest of democracy in medicine—that system which has brought to the people of the United States, the highest type of medical service to be had on earth."

It is hoped that the American Legion will adopt this plan as theirs, inasmuch as it is to their interest, and while we recognize this fact, it is also to the interest of every medical man in this country to preserve the present system of practice. The present plan of the government, if carried out, will eventually wreck our hospitals. The taxpayers should become vitally interested in another plan if it is constructive, while humanitarian as well as economical.

Medical men should be able to exert a tremendous amount of influence, not only for the public good, but to avoid pernicious legislation which is harmful both to the public and the profession.

While I am sure, that we with one accord, would gladly see the proper hospitalization of every veteran who needs it, and would serve without cost, if it be necessary, any veteran, if that veteran were unable to care for himself, yet our profession should stand with every economic force, to protect the resources of our country and

ourselves from that onslaught which is being constantly made to widen the door of hospitals, not only to veterans who could justly claim hospitalization but to those whose self-respect should restrain them.

In this connection, it may not be amiss to call your attention to the readiness of the National Federation of Federal Employees now numbering six hundred thousand, exclusive of judiciary, military, navy and other personnel which is large and would bring the total up to approximately one million. This Federation is watching intently the development of the present plan of building large veteran hospitals and will soon demand for members and their families, hospitalization and professional care—all told about two to four million may be expected to ask for such increasing service.

The doctors will become divided into classes—Government Doctors and Common Doctors—taxes will be higher—medical service will become more complicated.

Strike hard against any such socialistic propaganda—against such socialistic realizations. You owe it to yourselves and the people whom you serve.

The future usefulness of our profession is vitally wrapped up in rational methods of practice. As an organization, we must stand for those principles which underlie the structure of our government, and cooperate with those intelligent forces which oppose bureaucracy, with its tendency to destroy individualism and originality in this country.

The modern doctor is the recipient of all that has come through the ages. The people are his friends to aid and protect. Great is the profession in cumulative knowledge. It must wisely and beneficently distribute the blessings it has to bestow on the people. The people should respond in good faith, for in medicine there are no overlords; none so great that he may not fall, if he turns his face from the main object—the service of humanity. . .

ERIE COUNTY AND PUBLIC RELATIONS*

By LOUISE W. BEAMIS, M.D., BUFFALO, N. Y.

A MEETING like this where we exchange ideas and present our problems is important enough to warrant a day's absence from our work. As secretaries we owe it to our individual societies to bring home the ingredients with which to make a fine functioning cooperative society, alive and alert to the needs of its members, the public, and the state.

Erie County has tried to interest the public through radio talks three times a week. These talks are given by two young physicians whose names are not announced. The material is prepared by the A.M.A. and selected by a committee of 23 representative doctors, and adapted for our local use.

WGR allows us to use the radio free of charge, and the lecturer is announced as the "Doctor of the Air." The young men receive a slight remuneration for this—paid for by the Society.

It was found more satisfactory than when individual doctors spoke on their own specialty. There is no chance for criticism, and we feel the laity are being better informed on things medical. Such publicity deals in facts to which the public is entitled. The lay press and radio are delivering information often to the detriment of the public, who becomes misinformed and is unable to judge

the uselessness of the article or fact expounded. We feel this should be combated through education by the medical societies, who should be the leaders in the practice of medicine due to education and training.

Very often misinformation is given by faddists, cults or lay organizations. It is when there is an infringement on the rights of the physician through these lay organizations, who have interested themselves in matters pertaining to public health, that the medical societies should assert their own scientific training and leadership.

May I quote from an address by Dr. Harlow Brooks, New York, in the *Journal A.M.A.* of July 2, 1927, who said in part:

"Sanitation, epidemiology and the executive features of public health work must be considered only as specialties in medicine, just as we practitioners group ourselves as neurologists, surgeons, internists, and so on. Without a basic training in the elemental medical sciences there cannot be true specialization in such work any more than the surgeon can be permitted to practice his craft without a careful training in physiology, in bacteriology and in the other essential fundamentals.

"To such men the medical profession as a whole give it sincere confidence and full cooperation. I do not know of any exceptions. We have every confidence in all those specialists in public

* Address before Conference of Secretaries of County Societies, at Albany, N. Y., on September 15, 1931.

health who are legitimately specialists. We have a quite natural suspicion of those lawyers, politicians, business men preachers and otherwise unoccupied ladies, grouped so loosely and so thoughtlessly as 'social workers,' who do not have basic training or understanding of those subjects to which we have so seriously and with single-hearted zeal devoted our whole preparation and life.

"What does the physician in family practice resent in the activities of public health?"

"He resents nurses doing the work of physicians, making diagnoses and dictating treatment which the family physician shall carry out. Do you blame him?"

"He resents the underpaid time serving employee of the department who from the wealth of his inexperience minimizes to school children the work and ridicules the respect of their family doctor."

"This is all correctible. Nurses are nurses until they have studied medicine and legally qualified themselves as practitioners of medicine. They should not be allowed to do as an agent of public medicine, work which the law does not permit them to do as private individuals."

"Employment of young physicians at meagre salaries robs the profession of the material from which it should recruit its general practitioners, now the greatest need of the profession. I often tell my internes at graduation that the worst thing that could happen to them would be to receive a salary on which they could live, from some lay institution, in which the professional experience does not reward the service, for many of them later in life would not dare to give up their salaries and start out for themselves. Some of the brightest youngsters I have ever known have been ruined by such activities. They typify the non professional controlled society. Some of them are notorious for the ruthless exploitation of the young physician."

"Public medicine cannot be divorced from private medicine, except at a loss to both. The most potent and influential teacher of public medicine is the physician in contact with his patient. No public medicine can succeed that has not the endorsement of the average physician."

"The value and influence of the average practitioners are beyond the comprehension of the

executive who is himself not conversant with the details of medical practice, or who has through lack of experience estranged himself from the profession. He is likely to develop from his ignorance of real medicine and its problems a superiority complex of particularly inexcusable type. This is the disease from which many public health workers suffer, they are the ones who criticize the average physician."

Our Society is trying to solve some of these problems and in so doing is bringing in the younger men whose economic welfare is threatened. It is a reflection on the Medical Society that it fails to protect its component parts—the physician who through years of preparation is unable to advance on account of loss of independence and self-respect through the sale of his professional services to those corporations or organizations in need of his services. This prevents initiative and leadership on his part."

I feel the County Society through its Committee on Economics could be of great service to the new recruits to the medical profession each year. He should be taught that his independence which is essential for his best work be preserved, and that the personal relationship between himself and the patient is vital to the practice of medicine and for best service. This service to the individual young graduate would be invaluable, and a real constructive work on the part of the County Society."

As Dr. Olin West has said, "That the key to the whole situation and the work that medical organizations in this country must accomplish must, after all, be accomplished through the County Medical Society. The A M A can do a lot of things, and does try to do all it can. The State Association can do a lot of things, and some of the states are trying to do all they can do, but when you get right down to bedrock, neither the A M A nor the State Association can do anything right unless the County Society does something, and does it right."

As no society is stronger than its weakest link, it is paramount that each county become an active functioning integral part of the State Society, LEADING, COOPERATING and ENCOURAGING those measures which best serve constructively the profession and the community in which that County Society is functioning."

INTRA-ABDOMINAL HEMORRHAGE OF OVARIAN ORIGIN

By PAUL C. MORTON, M.D., NEW YORK, N. Y.

From the Surgical Service of Knickerbocker Hospital, New York

INTRA-ABDOMINAL hemorrhage of ovarian origin is probably not as infrequent a condition as the literature would make one believe. Cases reported up to 1931 number 93 but the subject, when discussed with any group of surgeons of the average operative experience, always brings to light one or more cases which have not been reported. A condensed survey of these cases is given in the table below:

TOTAL CASES REPORTED TO 1931....93

Ovary Involved.	
Right	25
Left	19
Not Given	49

Type of Cyst.	
Corpus Luteum	26
Follicular	5
Not Given	62

Preoperative Diagnosis	
Appendicitis	37
Ectopic Pregnancy	17
Cystic Ovary	3
Salpingitis	3
Exploratory Lap, or not given	33

Both Novak¹ and Shaw² agree that the corpus luteum develops between the 16th day to 23rd day of the menstrual cycle, with the height of the maturity about the 19th day. Accurate menstrual histories have not been given in the majority of the cases. R. K. Wilson³ gives a series of seven cases in which this information was accurately elicited. The time of onset of the symptoms ranged from the 8th day to the 26th day of the menstrual cycle, with the average time being 16-7/10 days. All of these seven cases showed by pathological examination the presence of lutein cells. These cases, and the survey of reported cases, would suggest that the hemorrhages are much more frequent in the corpus luteum cyst than in the follicular cyst. There are a number of cases reported, however, in which the onset of symptoms was in the very first part of the menstrual cycle. These cases give no pathological report as to the character of the cyst.

None of the cases included in this report were diagnosed accurately before operation. Schumann⁴ reports three cases, and Blakely and Farr⁵ five cases in which the diagnosis of hemorrhage from the ovary was made, but conservative treatment was followed and no confirmation of the diagnosis was possible. From the information secured from the literature and data available in the case reported herewith, it is difficult to give suggestions which might lead to a preoperative diagnosis. There is possibly one exception to this

statement; the absence of a history of injury, a normal menstrual history, and the clinical picture of an unmistakable intra abdominal hemorrhage. Under these circumstances, its possibility could be reasonably suspected. In those cases where the hemorrhage is only of sufficient amount to create a peritoneal irritation or to markedly distend the corpus luteum cyst without rupture, the diagnosis has almost always been acute appendicitis. R. K. Wilson gives 9 cases of hemorrhage of the right ovary entering the Surgical Service of the London Hospital, all with a diagnosis of acute appendicitis. During the same period 10 cases were admitted to the Gynecological Service of the same hospital with hemorrhage from the right ovary in 2 cases and from the left ovary in 8 cases. It seems safe to assume, as Wilson points out, that had the diagnosis been anything other than that due to a suspected pelvic pathology, they would all have been admitted to the Surgical Service. Unfortunately, he does not give the preoperative diagnosis in these cases, but assumes that they were not diagnosed correctly.

The case reported below is given as an example of hemorrhage from the ovary simulating ectopic pregnancy.

F.B., age 29, married, was admitted to Knickerbocker Hospital at 9:40 P. M., April 13, 1927. Her complaint was abdominal pain and vomiting. Forty hours before admission there was sudden, knife-like pain in right lower quadrant, causing her to double up and, within a few minutes, to lie down. An hour later there was nausea and vomiting but the pain had almost completely disappeared. She had a fairly good night. Twelve hours before admission there was recurrence of nausea and vomiting, with progressive weakness. Seven hours before admission, the patient fainted four times within an hour.

Her menstrual history showed a normal and usual menstruation in January, 1927. On February 2nd, two days before the usual time for her menstrual period, she began to flow and ran the normal course of five days without distress. On March 26th the menstruation was normal in every respect and this was the last period before admission. There had been one pregnancy about five years before, the child having died at one month.

Examination of the patient showed her to be acutely ill, pale, apprehensive, subnormal temperature, pulse 96 with diminished volume. The abdomen was tender and rigid throughout, more marked in the right lower quadrant. Pelvic examination showed the cervix to be firm and hard, uterus not enlarged, and no abnormal masses felt. There was well marked tenderness in the right

fornix. Blood count showed hemoglobin 55%, red blood cells 2,096,000, white blood cells 22,900, Polymorphonuclears 88%, small Lymphocytes 10%, large Lymphocytes 2%. Preoperative diagnosis of right ruptured ectopic pregnancy was made and operation performed at once.

FIGURE 1

Full view of corpus luteum cyst and point of hemorrhage.

The abdomen was full of fresh blood and large clots. The left tube and ovary were normal. There was no evidence of chronic inflammatory disease. The right tube was normal. The right ovary contained a corpus luteum cyst 3 cm. in diameter, from which fresh blood was oozing, and which was covered with a blood clot. This was the only source of bleeding found. The tube and ovary were removed. The following day a transfusion of 500 c.c. of whole blood was given, and the patient made an uneventful recovery, leaving the hospital May 1, 1927, nineteen days after admission.

Pathological examination by Dr L. C. Knox showed "a fresh corpus luteum with hemorrhagic center and well formed, large, lutein cells at the periphery, this being the portion of the ovary which has perforated the serous covering. The rest of the ovary is edematous, containing numerous small follicular cysts, but also showing much normal structure"

SUMMARY

1. Intra abdominal hemorrhage of ovarian origin is not as rare a condition as has been thought.

2. The diagnosis of this condition should be suspected in cases lacking a history of injury, giving a normal menstrual history, onset of symptoms after the 16th day and before the end of the menstrual cycle, and clinical signs of intra abdominal hemorrhage.

3. The diagnosis of those cases in which hemorrhage is of sufficient amount only to give peritoneal irritation or to markedly distend the corpus luteum cyst, cannot be accurately diagnosed.

4. Incidence of pathology is probably equal in right and left ovary.

RADIUM IN TREATMENT OF INOPERABLE DISEASED TONSILS WITH A NEW METHOD OF RADON IMPLANTATION

By J. COLEMAN SCAL, M.D., F.A.C.S., NEW YORK, N. Y.

SINCE 1922 I have been employing radium in the treatment of diseased tonsils which were, for one reason or another, not amenable to operation. The cases which were so treated were those in which surgery was definitely contra-indicated. As no other method of removal of such tonsils up to now has been perfected, any improvement in the condition of the tonsils should be considered a successful result. The patients considered inoperable were those affected with cardiac, pancreatic or kidney disease as well as haemophiliacs and those suffering from tuberculosis or syphilis. Included among these are also a number who positively refuse operation because of fear and physical dread of any operation.

In this procedure, the tonsils are not removed but are reduced in size, atrophied, and the symptoms produced by disease are alleviated. In every case radiated the tonsils did shrink and become fibrous.

Over 200 cases of diseased tonsils were radiated and the success attending this method of implantation of radon seeds, should be sufficient to permit the drawing of definite conclusions in regard to this therapy.

The chief objection brought against the treatment is that, because the action of radium cannot be controlled after the containers have been implanted, injury to normal structures adjacent to the tonsils which undergo radiation is practically inevitable. Inasmuch as the entire theory of radium treatment of the tonsil is based upon the established radio-sensitivity of lymphoid tissue, which is known to be far greater than that of skin, muscle or connective tissue, this objection can be immediately refuted.

With the present method, the amount of radiation used can be gauged accurately, making it possible to measure the precise dosage the tonsil will receive.

A 3-millicurie seed of radon will radiate 4 cubic c.m. of lymphoid tissue in a little over 4 days, delivering a dosage of about 200 millicurie hours. Since the average tonsil is about 2 c.m. in diameter it will readily be seen that the tonsils only received the radiation, the action beyond the capsule being *nil*.

The platinum radon seed, which has an initial activity of about 3 millicuries, decays at the rate of 0.747 per cent of its activity each succeeding hour, so that at the end of four weeks activity has practically ceased. The highest value, therefore, is naturally during the first week following application, since the period of half-decay of radon is 3.85 days. Thus the maximum dosage for each

millicurie of contained radon amounts to 133 millicurie hours.

The caustic rays are eliminated by filtration, leaving only the therapeutic gamma radiation which acts without burning or causing other tissue destruction. Antoine Lacasagne, bio-physicist of the Currie Institute, has shown that a filter of 0.30 mm. platinum will produce no destruction, if less than 7 millicuries of radium emanation is used, then only after a period of 12 days is necrosis observed. In all cases treated by me the radon seeds were made of a 0.30 millimeter platinum filter, each seed containing from 1.5 to 3.0 millicuries of radium emanation.

It is also essential to implant the radio-active center so that every part of the tonsil mass will be subjected to an equal amount of radiation. These desired results can be brought about either by the use of needles containing radium element, or of "seeds" of either gold or glass, filled with radon (radium emanation). Far greater satisfaction, however, has been obtained by employing the removal platinum radon seed, designed by Joseph Muir of New York, which embodies all the good features of the applicators just mentioned, and in addition possesses several which are peculiar to itself.

Glass seeds without metal filtration permit passage of caustic radiation, which induces so much necrosis that the use of such applicators in the tonsil is inadvisable. Gold, while providing an excellent screen against caustic radiation, cannot be sealed as completely as can glass, so that those using gold containers are never absolutely assured against leakage, which not only makes dosage uncertain, but may do grave injury to surrounding tissue. Both glass and gold seeds must be left permanently in the throat, and this, in nervous patients especially, constitutes a very grave objection. The life of the radon contained in these tubes covers but a short period, after which they become inert. They are either surrounded by fibrous tissue or, if infected, are sloughed out. The removable platinum radon seed which I now use is about 4 millimeters long, with a content of approximately 3 mc. of radium emanation. A strong silk thread, by which it can be removed when it has served its purpose, is attached to each seed. Screenage is of 0.3 mm.—thickness of platinum—enough to eliminate practically 98.5 per cent of the caustic beta radiation. These seeds can be sterilized by boiling, being absolutely unaffected by any degree of heat, whereas gold seeds are likely to "spring a leak" if subjected to high, moist temperature.

Usually between the third and fourth week following the radium application, inspection of the

tonsil will show that it has already shrunk to a third or even a quarter of its former size. Thereafter, until six months or more have elapsed since implantation, still further reduction will be noted. The open crypts will be entirely obliterated and the focus of infection thus eliminated. If the seed has been properly placed in the center of the mass, the end results should be fully apparent between the sixth and the ninth month, at which time nothing more than a small fibrous mass behind the anterior pillars should be visible.

This process of atrophy takes place without any injury to adjacent tissue. The author has had his own tonsils radiated and at the end of two months he had them removed, surgically. Examination by Dr. Maurice Goldberg, who was the pathologist at the Beth Israel Hospital gave the following findings:

"Section of tonsils shows a considerable diminution of the lymphatic element which is replaced by fibrous tissue. A great deal of the fibrous tissue has undergone hyalinization. The chronic inflammatory process is not uniformly distributed. There is a great deal of nuclear destruction. In parts the lymph follicles have entirely disappeared, while in other parts they are rather large, poor in lymphocytes with proliferation of the genetic center.

"Some parts of the epithelial covering stain very poorly."

It will be seen that a destructive process takes place in the cell in which the cell-bodies swell and the nuclei undergo hyperchromatism and are broken up. This is followed by exudation and infiltration of the lymphocytes, with formation of granulation tissue. Thus the lymphoid tonsil disappears and what is left is transformed into a fibrous mass.

FIGURE 3

A.C. Before treatment with radium.

In many arthritic and rheumatic patients treated by this method, where the diagnosis was made by a very competent attending physician, the joint and muscle symptoms disappeared within a fortnight after radon implantation. Even when these symptoms still persisted, relief and improvement were admitted. Sore throat was eliminated in practically all cases. In a few patients who had given histories of repeated attacks of tonsillitis, often complicated by peritonsillar abscess, the result was not ideal. This partial failure I attribute to the presence of fibrosis induced by repeated inflammation, for it is upon lymphoid tissue that radium is especially effective. But even in such circumstances, the crypts, and therefore the foci of infection, were eliminated.

In about five per cent of my cases treated by this method, I was not satisfied with the end result. While the tonsils showed diminution in size and relief of symptoms, they were still enlarged and pathological in appearance.

Under such circumstances, I found it necessary to make a second implantation. When failure has occurred, I have attributed it to failure to implant directly in the center of the tonsil, so that some portion of the mass did not receive its due amount of radiation. In one or two cases where the seeds were placed superficially, they fell out and were swallowed by the patient, but no untoward results followed this accident. The author, himself, swallowed two potent radon seeds without any bad effect.

In the series of cases mentioned here, one patient developed a peritonsillar abscess two weeks after implantation. The cause could not be ascertained since the abscess cavity was not near the implanted area. This patient had very diseased tonsils and the implantation may have produced a low grade inflammation in the tonsils which resulted in the subsequent abscess formation.

TECHNIQUE:

Dr. Muir, the designer of the seed, has recently worked out an improved method of inserting the seed in the tonsil which insures its remaining in the exact position in which it is originally placed. Instead of placing the seed in the slot as has previously been our custom, it is put into the *point* of the implanter, the thread end being thrust in first. (Fig. 7-A.) The attached thread makes a loop which protrudes from the point. The obturator is inserted and pushed home in the same manner as previously, and the seed is thrust into the tissue. (Figure 7-B.) The thread makes a loop at the back of the seed and is then brought forward along the barrel of the implanter so that when the instrument is withdrawn it protrudes from the puncture. Before placing the seed in the implanter, the thread should be cut off to a length of not more than 2.5 cm., so as not to interfere with deglutition or otherwise inconvenience the patient. (Fig. 8-A and B.) The loop at the back of the seed prevents its dislodgment by any traction which might be brought to bear upon the protruding thread-end. It also stabilizes the position of the seed so that there is no

chance of its migrating from the precise point where we placed it.

The presence of the thread in the throat does not cause the patient the slightest inconvenience; he is able to speak and swallow as under normal condition. Though a few patients have complained of sore throat, examination has never shown any inflammatory reaction, and a little local palliation suffices to make any such symptoms disappear. The seed is removed on the fifth day, which is accomplished merely by seizing the thread with forceps and drawing the seed out. The entire procedure is carried out in the office, no hospitalization of any kind being necessary.

CONCLUSIONS:

While I still recommend tonsillectomy in operable cases, over eight years' experience has con-

FIGURE 1

Technique of radon implantation

vinced me that in the implantation of radon seeds we have a satisfactory substitute for use in inoperable cases. Neither morbidity nor mortality attends the procedure, and the technique has been so developed that by the method here described we are able to obtain complete atrophy of the tonsils without producing any inflammatory reaction or injury to the structures surrounding the tonsils. There is no post-operative hemorrhage, no danger of lung abscess, no aspiration pneumonia, and no middle-ear involvement. The procedure is practically painless, can be performed in the office, and the patient permitted to pursue his normal mode of life without inconvenience of any description. Of the number of cases treated, twenty per cent were affected with joint symptoms, twenty-eight per cent were cardiacs, three per cent haemophiliacs, five per cent exophthalmic goitres, ten per cent diabetics, eight per cent arteriosclerosis, while the rest were treated for "fear of operation."

There being no traumatism, we do away with the presence of subsequent scarring and adhesions, so frequently seen after tonsillectomy, even when performed by a skillful operator.

In hemophiliacs the bleeding following the

FIGURE 8

needle puncture is sometimes annoying, but usually ceases after proper local treatment.

RECORDED AND RESIDENT DEATH RATES IN NEW YORK STATE

No. III — Cancer, All Forms: 1927-1930

By J. V. DE PORTE, Ph.D., ALBANY, N. Y.

Director, Division of Vital Statistics, New York State Department of Health.

OF late years, cancer has taken a dominant place in the minds of all who are concerned with the physical welfare of mankind. Numerous efforts have been and are being made to determine the true prevalence and trend of mortality from malignant growths, but mainly because of the inadequacy of the basic information, statistics on cancer are quite unsatisfactory. Competent practitioners and specialists have stated repeatedly that a large proportion of the deaths ascribed to cancer are really due to some other cause, while at the same time a number of deaths under other rubrics are really caused by cancer. In a letter to the writer, an eminent pathologist stated that there are "no reasonably accurate figures on cancer" and that any conclusions drawn from the published quantitative data "can never be reliable and usually will be misleading."

The allocation of deaths from cancer makes but a slight difference in New York City and the Rest of State, but affects considerably the rates of Urban and Rural upstate sections. For example, the rate of the urban territory in 1930 is reduced 5 per cent while the rural death rate is increased 13 per cent. The apparent excess of mortality from cancer in urban New York gives place to a higher resident rural rate. It is important to add here that the death rate of the rural territory is, of course, directly influenced by the unfavorable age composition of its population. The Division of Vital Statistics is now analyzing the resident cancer mortality according to age. The results will be published as soon as they are available.

Cities. The resident cancer death rates of the majority of the cities are lower than the recorded rates. In 1930, in the group of cities over 25,000

Year	New York City		Rest of State		Urban		Rural	
	Recorded	Resident	Recorded	Resident	Recorded	Resident	Recorded	Resident
1927	113.3	113.3	126.2	126.2	128.4	121.5	121.1	137.1
1928	115.2	115.2	126.4	126.4	133.0	127.1	112.9	127.2
1929	114.8	115.2	130.3	129.8	133.1	126.0	122.0	139.4
1930	116.7	116.9	131.5	131.2	136.8	130.3	120.2	136.3

Death Rates per 100,000 Population

Should one, therefore, forego an analysis of mortality from cancer because of the large error contained in the figures? The answer to this question is clearly *no*. There would be no progress in medical or any other sciences if investigators, in blissful idleness, awaited the day when the entire truth became evident. A death rate is in a sense a theory which is constantly being made more accurate by the greater accumulation of knowledge. It seems entirely reasonable, while recognizing the large degree of error in cancer diagnosis, to apply to the published death rates numerical refinements which the available information makes possible. One of these is correction for residence.

When a family physician diagnoses a case of cancer he usually refers the patient to a specialist. Hence, communities with superior facilities for the treatment of cancer may, for this reason alone, show high recorded death rates. The table below shows the death rates from cancer per 100,000 population, recorded and corrected for residence, in New York City and in the urban and rural upstate territories in 1927-1930:

population, the resident rates were higher in the following five cities:

	Recorded	Resident
Yonkers	80.3	89.9
Mt. Vernon	87.0	96.7
New Rochelle	91.7	106.4
Elmira	171.4	173.6
White Plains	77.2	82.7

Rural Area of Counties. The resident cancer rates of the rural areas of most of the counties are higher than the recorded rates. In 1930 the rural resident rates were lower in only seven counties:

	Recorded	Resident
Chemung	102.8	93.8
Essex	127.7	119.7
Ontario	195.9	179.6
Orleans	123.8	118.2
Putnam	130.4	123.1
Schenectady	104.2	99.7
Westchester	234.9	104.9

MEDICAL LEGISLATION

The Legislature of the State of New York is now in the middle of its session, but the most important lines of its action are not yet clearly revealed. The cultists are evidently following their usual tactics and are waiting for the closing days of the Legislature so that their opponents may not have time to refute their arguments and 'testimonials'. Workmen's Compensation bills may be expected and the proposals of the Governor's Health Commission in regard to public

health administration will probably be put into legal form. All these major bills and many minor ones are being closely watched by the Committee on Legislation of the Medical Society of the State of New York and information regarding them is transmitted promptly to the chairmen of the legislative committees of the county medical societies with the expectation that the individual members will express their opinions of them to their local legislators.

THE HOUSE OF DELEGATES

Whenever a new movement in public health is proposed, there are differences of opinion among both physicians and laymen. Physicians sometimes resent the dictation of laymen who tell them what they shall do; and on the other hand, laymen are often impatient with physicians who ask embarrassing questions regarding the probable effects of the new proposals of investigators, statisticians, and welfare workers.

The Health Commission appointed by Governor Franklin D. Roosevelt in May, 1930, made a report in the spring of 1931, which was printed in abstract in this Journal of February 15, 1931, and in full in this Journal of October 1, 1931, page 1208; and in the meantime the House of Delegates meeting on June 1, 1931, had instructed the Standing Committee on Public Relations and that on Public Health and Medical Education to act jointly in studying the findings of the Governor's Health Commission and reporting its recommendations to a special meeting of the House of Delegates. The report of the Joint Committee was printed in this Journal of January 1, 1931, page 29, and was considered by the House of Delegates at a special meeting held on January 14, 1931. A full report of the proceedings at that meeting is printed in this Journal beginning on page 213.

The general topic considered by the Governor's Health Commission was the participation of governmental bodies in health matters. After nearly a year of study by the Commission, its findings were considered by the Joint Committee of the Medical Society of the State of New York over a period of six months, during which time hearings were held in several sections of the State so that representatives of every county medical society would have the opportunity to express their opinions regarding the suggestions of the Commission. Finally, on January 14, 1931, the official representatives of the medical societies of the counties and the State, discussed the recommendations freely and without restraint.

A remarkable degree of harmony and good judgment has been shown by all the parties concerned in the investigations throughout the entire

course of the deliberations; and agreements were reached in over eighty per cent of all subjects under consideration,—a new record for agreements between the laity and the medical profession.

There were ten major subjects considered by the Joint Committee of the House of Delegates, as follows:

1. State Aid for local public health work: It was felt that the subject should be considered in the light of each individual activity as it arises.

2. County Health Departments: While their principle was approved, yet the decision was that the form, time and manner of their organization should be determined by future developments.

3. Tuberculosis Sanatoria: Most of the recommendations of the Governor's Commission have already been enacted into law.

4. Venereal Diseases: The principle of their control by public health authorities as communicable diseases was approved, but the manner of the control should be the same as that of other communicable diseases, with treatment of individuals who otherwise could not obtain treatment.

5. Cancer: A campaign for educating the people was approved.

6. Maternal and Infant Hygiene: The general principles of public health work in the protection of mothers and infants were approved.

7. School Hygiene: A working agreement between the departments of Health and that of Education was suggested.

8. Orthopedics: The general principle of State Aid to the indigent cripples was approved.

9. Public Health Nursing: Since the recommendations of the Governor's Commission were indefinite, no special action was taken.

10. Industrial Hygiene: This subject is so broad and far-reaching that special studies of it will be required.

The subject of State Aid came up toward the close of the session, and the Joint Committee was requested to consider it and report to the next regular meeting of the House of Delegates.

MOULDS IN HUMAN DISEASES

The January number of the Journal of the Medical Association of Georgia contains an article on mycology in its relation to human diseases, and lists ten diseases which are caused by moulds or fungi, and which are significant to physicians of Georgia. These ten diseases are probably as prevalent in New York State as they are in Georgia.

While they are known to doctors generally, yet if most doctors were suddenly to undergo an examination and be asked to name them they would probably hesitate over some of the more uncommon ones. The authors discussed these moulds in outline only, and in the following order:

1. The epidemophitoses of which ringworm is the most common example. Probably every doctor would put ringworm first on this list of fungus diseases.

2. Actinomycosis produces swellings in the skin, or more commonly in the lungs and sinuses of both man and cattle. The fungus is the cause of the disease called "lumpy jaw" in cattle, but the authors say that it cannot be transmitted to man. The disease in man usually affects the lungs and is mistaken for tuberculosis.

3. Blastomycosis is a yeastlike fungus. In Georgia its usual manifestation is a pustular lesion of the webs of the fingers. The authors say that it is "not uncommon."

4. Sporotrichosis is caused by a yeastlike fungus which produces an ulcer on the side of the hand and lines of vesicles along the lines of the lymphatics. This disease is fairly well known in New York.

5. The Broncomycoses form a group which generally enter the body by way of the lungs and produce conditions which are mistaken for tuberculosis. Practically the only way of recognizing the disease is by finding the fungi in the sputum.

6. Tinea Versicolor is a superficial skin disease with the formation of brown scales. Patients usually seek relief for the discoloration of the skin rather than any actual suffering.

7. Erythrasma is cited by the authors as a disease almost exactly like actinomycosis.

8. Favus produces a thick scab on the scalp. It is rather common among mice, and is among the contagions for which a search is made at quarantine.

9. Trichomycosis is a harmless condition which produces small nodules attached to the hair of the axilla, and is the usual cause of colored perspiration.

10. Sprue. Sprues constitute a group of conditions of the mouth and sometimes of the intestines. They produce lesions varying from slight milk-like patches to severe enteritis, and even death. Tropical sprue is likely to be chronic, and frequently ends in death. Milder forms of sprue are often found in the mouths of patients who may suffer only slight inconvenience, or may have a systemic infection. Observant health officers frequently run across these lesions in the mouth. These conditions deserve far more study than they are receiving. They are not common, and so they are not classified with any degree of completeness. They do not seem to be great factors in public health, and yet they are deservent of study, for no one can tell when they may become serious public health problems.

LOOKING BACKWARD

This Journal Twenty-Five Years Ago

Chain Drug Stores: This Journal of February, 1907, contains a leading article advocating the organization of a chain of drug stores by the medical profession, and says:

"Let us suppose the American Medical Association had appointed a committee to incorporate such a company under the laws of the State of Illinois, with an eventual, unlimited, capital stock, and an initial issue of \$30,000.00, par value of shares, \$10.00 each. Such an organization could be perfected, and the expense of securing the subscriptions for a first store could be paid at an expense of not more than \$2,500.00. New stock authorizations could be made from time to time to meet the requirements of the business and its development.

"The sole purpose of such a corporation would be to capitalize, establish and operate a system of co-operative stores in the interests of thousands of conscientious, honorable physicians who, for the sake of their good reputations and the welfare of their patients and public at large, feel the urgent need of some systematic plan by which they may be assured of:

"1. Having only the highest quality of drugs dispensed on their prescriptions.

"2. To prevent substitution without their knowledge or consent.

"3. To prevent the indiscriminate sale of nostrums.

"4. To prevent the sale of poisons excepting for specific purposes, as prescribed.

"5. To insure the prompt and proper filling of prescriptions.

"6. To establish a check system to obviate errors.

"7. And for the multitude of other reasons which would tend to protect the physician in his practice and reputation, and the public against dangerous mistakes, indiscriminate substitution, and other well-known abuses in the filling of prescriptions.

"The company assuming the responsibility of making proper connections with the manufacturers of high-grade drugs, physicians' supplies and instruments, whereby only first-class goods might be had at lowest possible cost, under a system guaranteeing their purity and freshness. Every article dispensed by the system of stores to bear the Association label guaranteeing its purity."

The whole article covers five pages, and sets forth the scheme in great detail, even to its probable profits.

MEDICAL PROGRESS

The Vago-Gastro-Cardiac Reflex and Its Clinical Application.—There is a group of patients, says C. Farmakidis, in the *Archives des maladies du coeur, des vaisseaux et du sang* of September, 1931, in whom the usual methods of clinical examination reveal no cardiac pathology, and yet there is a state of dyspnea after exertion that cannot be explained by the physiologic condition of the other organs, but must be related to a hypotonicity of the myocardium. This hypotonicity is brought out by eliciting what the author calls the vago-gastro-cardiac reflex, which is done as follows: With the patient lying on his back, the area of absolute dullness of the heart is marked out by means of percussion, and the exact position of the apex noted. Then the patient is asked to flex his knees and thighs in such a way as to relax all the abdominal muscles, and while he holds his mouth open the physician carries out a prolonged massage of the abdominal region corresponding to the anterior surface of the stomach. Then the area of cardiac dullness is again mapped out. In a certain number of individuals a dilatation of the left heart alone is observed, and the apex is displaced downward and outward. In other words, there has been an increase of the longitudinal diameter of the heart. The phenomenon may be very brief, and it may be slow in appearing, so that sometimes several observations and mappings must be made in order to catch the right moment. The individuals in whom this vago-gastro-cardiac reflex is positive are for the most part subjects with hyperchlorhydria and signs of vagal hypertonus. In the absence of any sign of valvular disease, the dyspnea experienced by these persons must be due to an alteration of the myocardium, a latent hypotonicity of the cardiac muscle. If this is the case, it will be proved by the effect of administration of cardiotonics, which will overcome the sense of suffocation that follows exertion attended by dilatation of the left heart, caused by the mechanical excitation brought to bear upon the abdominal region as indicated above. Roentgenograms show very clearly the increase of longitudinal diameter of the heart after excitation of this region in cases where the reflex is positive. The reflex is useful for revealing latent hypotonicity of the myocardium caused by various conditions, such as hypertension, intoxications, and a number of physical causes. Its simplicity and the ease with which it can be elicited place it at the disposal of every practising physician.

Roentgenography of Liver and Spleen.—The possibility of making the liver and spleen visible

roentgenologically offers a valuable addition to our present methods of examination, say L. Popper and Erwin Klein, since in this manner not only the size and form of these organs can be established, but also various changes within the substance of these. The contrast substance injected is a colloidal thorium dioxide solution. After proving the harmlessness of the substance in animal experimentation, Popper and Klein determined to test its value in human beings. But owing to their observation that the substance continues to give shadows of undiminished intensity in liver and spleen for months after its injection in animals, from which they concluded that little or none of it was being excreted, they proceeded with great care, and injected it only into 12 patients with cancer in a far advanced state, in whom the known radioactivity of thorium could do no harm at a late period, such as might be the case even after years in patients not already predestined to die at an early date. The injections were well tolerated in all cases and caused no secondary symptoms. The first roentgenograms were taken after 24 hours, but it was found that the shadows were at their best after 3 to 5 days had elapsed following the injection. Moderately good shadows were obtained with 36 c.c. of the thorium preparation employed, but for the maximum clearness 60 to 90 c.c. was necessary; larger amounts did not improve the results. Before taking the picture the intestine should be relieved of gas as fully as possible, since gas bubbles may project into the liver shadow and give a deceptive result. All the roentgenograms permitted an unequivocal judgment concerning the size and form of both liver and spleen. Since all were cases of carcinoma, it was only metastases that were to be taken into consideration. The results in four of the cases were confirmed at autopsy. One of these showed in the roentgenogram an extensive tumor of the right lobe of the liver, which appeared as a large filling defect. The spleen in most cases showed up as strikingly large in comparison with most of the findings that have been reported in advanced cases of carcinoma. In 2 cases that came to autopsy 60 per cent of the thorium dioxide could be recovered from liver and spleen, and in 1 case 97 per cent was still discoverable 2 months after injection. Great caution is therefore urged in the adoption of this method of exploration.—*Münchener medizinische Wochenschrift*, October 23, 1931.

Transitory Hemiplegia Due to Nicotine.—On the basis of 4 illustrative cases, F. Külbs discusses in the *Klinische Wochenschrift* of Novem-

ber 21, 1931, the connection between the abuse of tobacco and the appearance of cerebral symptoms such as headache, vertigo, and weakness of memory. In some cases it is possible that organic changes of an arteriosclerotic nature may lie at the bottom of this symptom complex, and the connection with smoking may, in older persons, be debatable. But when these phenomena are present in youthful subjects and disappear upon the enforcement of abstinence from smoking, there be can no doubt of a causal relationship. In the cases cited, which were in 3 men between the ages of 21 and 38 and 1 woman of 40, transitory manifestations of paralysis appeared, taking the form in the men of hemiplegia and disturbances of speech, and in the woman of motor aphasia. Syphilis could be excluded in all. In every case the phenomena were preceded by general disturbances of such a type that the mental and physical efficiency was considerably diminished, or headaches, paresthesias, and vertigo were present. Objectively the abuse of tobacco could be established by such symptoms as leucocytosis, increased basal metabolism, and marked nervous and vasomotor irritability. Since in all these patients there was a complete cure within a brief period after smoking was forbidden, one may well assume that tobacco had caused vasoconstrictor disturbances such as are observed in migraine. But in all cases a migrainous tendency, even of an atypical character, could be excluded. Hence it is absolutely necessary to assume the occurrence of transitory spasms. Since we know that after abuse of tobacco intermittent spasms of the coronary arteries may appear, and possibly also of the intestinal vessels, it seems justifiable to admit analogous processes in the cerebral vessels as phenomena of intoxication. We know that nicotine may have a markedly constricting effect upon the arteries, since it acts upon the vasoconstrictor nerves and the smooth musculature. It is impossible to say whether in these cases an arteriosclerosis of notable degree was present or not. The general view today is that true angina pectoris, which attacks young persons who abuse nicotine, develops on the soil of arteriosclerotic vascular changes. This point of view may, therefore, be accepted, if the threatening symptoms cease after abstinence from tobacco, and the patient maintains his efficiency for years or decades, and disappears when the toxic noxa is re-created; for spasm belongs among these disturbed.

The Etiology of Bronchiectasis. — In order to obtain a clear understanding of pulmonary pathology, Milton S. Lloyd requests the reader to keep constantly in mind the conception that each hemithorax is a closed air-tight cavity in which the lung is expanded by a negative pressure. Normally there is a definite and fairly

constant ratio between the intrabronchial and intrathoracic pressures. The constancy of this ratio depends upon the elasticity of the lung tissue and its variation depends upon the respiratory excursion. The entry of most abnormal conditions into the field upsets this relationship, and the change is reflected on all the surrounding structures—mediastinum, diaphragm, chest wall, and even the vertebral column. In considering bronchiectasis we are concerned only with those factors which cause a decrease in the volume of the lung. Such factors are chronic atelectasis and chronic inflammation. Since both of these processes transmute themselves into a fibrosis, the ultimate cause of pulmonary shrinkage in all cases may be said to be pulmonary cirrhosis. This loss of volume sets up a mechanical imbalance in the chest, which results in an outward traction on the bronchial walls and is followed by changes in the position of the surrounding structures. If various adjustments combine to satisfy the pulmonary contraction completely, further tendency to distortion, including that applied to the bronchial walls, will be relieved. But where a high degree of tension continues to exist, after the maximum possible compensatory changes have taken place, bronchiectasis will result. The degree of bronchiectasis depends upon the end balance between loss of volume on the one hand, and accommodating changes on the other. If the counteracting changes are moderate, the degree of bronchiectasis is moderate, and if the counteracting changes are grossly inadequate, the degree of dilatation is severe. Lloyd shows that it is impossible for pressure from within due to a cough or to the accumulation of excessive secretions to produce a bronchiectasis. He says he has never seen a dilated bronchus unassociated with pulmonary fibrosis and that even in the so-called congenital dilatations, the antecedent cause lies in an intrauterine pneumonia or pneumonitis which fixed the atelectatic lung *in situ* and prevented its expansion at the time of birth. He reports a series of cases and illustrates by diagrams the mechanical adjustments which may take place in the chest as a result of unilateral pulmonary shrinkage.—*New England Journal of Medicine*, December 10, 1931, ccv, 24.

The Influence of Lumbar Puncture Upon Cardiac Rhythm.—Paul Veil, writing in the *Archives des maladies du coeur, des vaisseaux, et du sang* of November, 1931, makes a report on studies he has undertaken with reference to possible modifications in the electrocardiogram during the course of a lumbar puncture. Avoiding too rapid or too slow a withdrawal of spinal fluid, he observed that it was nearly always necessary to withdraw 10 c.c. before any modification of the rhythm of the heart appeared, and that the total duration of the puncture should considerably exceed a minute. The patient was in

each case specially isolated to avoid the effect of other human contact. It was astonishing to note in some cases considerable modification, and in others none at all. The first studies were made regardless of diagnosis, but it was soon observed that the only patients in whom the rhythm was modified during puncture were those with lesions of the central nervous system. Thereafter the studies were confined to tabetics, encephalitics, hemiplegics with cerebral arteritis, subjects suffering with cerebral compression, or those who simply presented signs of radiculitis (radicular sciatica). While the alteration of rhythm is constant, it varies widely from one individual to another, even in the same disease. Sometimes there was a marked slowing down at the end of the puncture, even assuming the form of nodal bradycardia. The most frequent observation was the spontaneous appearance of flutter waves, shorter and shorter in the course of the puncture, such as some subjects exhibit upon ocular compression. Again there were simple changes of ventricular complexes, of great diagnostic value in that they were isolated and appeared only during puncture. Sometimes again there were cyclic modifications, now isolated, now associated with other rhythmic variations, with regular phases of acceleration and retardation. It would be premature to attempt at the present time to establish the diagnosis of the nature and localization of the lesion by the variety of the rhythmic troubles, or to suggest any hypothesis as to the mechanism of the trouble in a given case. Practically, all that can be said is that the existence of central nervous lesions is revealed in a constant manner by modifications of cardiac rhythm in the course of a lumbar puncture, and that these run parallel to those of the cerebrospinal fluid, as shown by cytologic examination. One might even say that they appear to be slightly more perceptible than the latter.

Recent Observations on the Pituitary Body.

—In a review of the varied activities of the pituitary body, W. Langdon Brown characterizes this gland as the leader in the endocrine orchestra. Anatomists in the past were struck with the idea that it resembled a little shrunken brain, which responded to or repeated the action of the big brain above. Modern research has shown that there is more in this idea than was supposed in the nineteenth century. Taking up each structure in the pituitary body, the *anterior lobe* contains both eosinophile and basophile cells. The growth hormone, derived from eosinophile cells, is responsible by overaction for gigantism, hemihypertrophy, and acromegaly, by underaction for dwarfism and progeria. The anterior pituitary produces two hormones from basophilic cells. Overaction of these cells produces virilism; underaction of both lobes produces Fröhlich's syndrome. The anterior lobe produces two other

hormones: The first is concerned with the reproductive function, assisting in the formation of the corpus luteum and in the rhythmical changes produced in the uterine mucosa to receive the ovum. Estrin is powerless to effect this in the absence of pituitary. The second of these hormones is concerned with the metamorphosis of such animals as go through this phase from a larval to an adult stage. The anterior lobe also contains the so-called chromophobe cells, whose function is unknown except that an adenoma composed of such cells diminishes pituitary function. The *pars intermedia* seems to belong functionally to the posterior lobe, but possesses the specific function of influencing the adrenal medulla in respect to pigmentation. The *posterior lobe* has been known for some years to be the source of pituitrin. Kamm and others have shown that it really contains two active principles, *oxytocin* or *pitocin*, which stimulates uterine contractions, and *vasopressin* or *pitressin*, which raises blood pressure, causes diuresis, and antagonizes insulin. The oxytocic effects seem to be purely chemical. The ovarian hormone will stimulate its secretion, while the luteal hormone inhibits it. In this way the corpus luteum maintains pregnancy; its destruction inevitably leads to abortion. The vasomotor effects of pitressin have been rather overshadowed by those of adrenaline, yet the pressor effect of emotion would be more likely to be produced by the gland nearer the emotional centers. There has been a tendency to ascribe diabetes insipidus not to the pituitary but to the overlying diencephalon. Since the posterior pituitary produces an anti-diuretic hormone, which will act on a denervated kidney, the logical conclusion would appear to be that, even when the diencephalon is responsible, it must act, not through a nervous, but through a chemical mechanism and this lies in the pituitary. After discussing the effect of pituitrin on carbohydrate and fat metabolism, and as a galactagogue, Brown traces the relationship of pituitary disease to some of its psychological accompaniments. It thus seems that nowhere are chemical and nervous factors so closely associated as in the pituitary-diencephalic region; primitive emotions and fundamental instincts cluster thick around it, and through it the rhythm of life is largely regulated.—*Practitioner*, December, 1931, cxxvii, 762.

Dietetic Prophylaxis and Treatment of Gallstone Disease.—The varying nature and long course of gallstone disease make it impossible, says B. Molnar, in the *Deutsche medizinische Wochenschrift* of November 20, 1931, to draw up a strict dietary regimen. The diet must perforce be adjusted to the requirements of the individual condition. Carbohydrates are harmless for the liver cells, do nothing to promote secretion and emptying of bile, but have a fattening effect, and

when consumed in large amounts may hasten the development of diabetes in persons having a tendency in that direction. Proteins irritate the liver cells, promote bile secretion, may cause colic in persons with a tendency to allergy, and they also have a constipating effect. The most injurious are the animal proteins, especially meats. Fats facilitate the emptying of the gallbladder, but may injure the liver cells, when roasted they encourage secretion of gastric juice, increase the emptying time of the stomach, and may thereby produce slow and painful gallbladder contractions, sometimes they contain cholesterol, some times they facilitate resorption of the latter, they have a very fattening effect. The many evil characteristics of fat do not militate against the good effect of the olive oil cure. Fats are ingested as a steady diet, while the oil cure lasts only a few days. The patient on a fat poor diet is allowed to take the oil cure from time to time. The best fats after oil are fresh butter and cream. Green vegetables, salads, and fruits contain hardly any protein, fat, or cholesterol, they have a good effect upon intestinal function, and are to be highly recommended. In functional disturbances of the liver, protein and fat intake should be limited, when the gallbladder is hypertonic fat should be used with great caution, when it is atonic, the cholagogue action of oil, butter, and cream should be utilized.

The Prognostic Value of the Oculocardiac Reflex in Tuberculosis—Carlo Scotti writing in the *Riforma medica* of November 23, 1931, reports the results of studies carried out during the course of a year upon 270 tuberculosis subjects, nearly all of whom were pulmonary cases. The reflex was followed up daily in the different stages of the modifications of their disease, so that it was not difficult to form a judgment as to its parallelism with the evolution of the tuberculosis. All the tests were made with the patients lying down in a state of relaxation so far as this could be obtained, and an attempt was made to remove as much as possible all influence of emotion, of menstruation, and of food, which constitute factors by no means negligible in the results. The examinations took place between 9 and 10 o'clock in the morning, with the patients fast and well rested after a night's sleep. An oculocompressor apparatus was used, but in some cases this was followed by digital compression and little difference was observed in the relative counts. In a first group of 80 individuals in whom the disease was running a mild course, the oculocardiac reflex was found present in 69, inverted in 1 and absent in 10. A second test on the same group 2 months later showed 60 positive, 3 inverted and 17 negative. The 9 individuals who had left the positive

group had all been suffering acute exacerbations of their disease, with pleurocortical or bronchopneumonic complications. Summarizing all his results, Scotti found the reflex present in 86 per cent of cases with good prognosis, inverted in 1.25 per cent, and absent in 12.50 per cent, on the first examination, the second examination revealed its presence in only 75 per cent. In severe cases with unfavorable prognosis it was present on first examination in 10 per cent, and on second examination in 11.25 per cent. He therefore concludes that the absence of the reflex gives an indication of the extent of the toxemia, and permits the making of an almost uniformly unfavorable prognosis.

Constipation and Right-Sided Ptosis—J. V. Fiddian says dyschezia is a relatively harmless disorder, due to the imperfect functioning of the rectal reflex. It is not so much a disease as an adaptation to the civilized conditions of life. The most logical method of dealing with it is by the use of the periodical simple enema, and not by deranging digestion and absorption by the use of drugs in order to fill the rectum to the threshold of stimulation. Cecal stasis is fairly prevalent and is not relatively as harmless as dyschezia. In the author's experience during a period of three years, among 975 persons with normally fixed colon no case arose requiring operation for an abdominal complaint, out of 325 persons with prolapsed colon, in the same period, there were 37 whose disabilities were sufficiently severe to lead them to consent to operation. These 37 patients were found to have prolapse of the cecum and ascending colon. The failure of many abdominal operations to relieve the symptoms for which they were undertaken has been due to failure to recognize the presence of right-sided ptosis. This condition is frequently associated with appendicitis, and when it is, failure to fix the colon may lead to relative failure of the operation to afford relief. The operation of colopexy, as devised by Waugh, seeks a normal fixation of the colon. After the appendix has been removed, an incision is made into the peritoneum in the angle between the ascending colon and the flank. A pocket is made by stripping up the peritoneum from the flank, the colon is rolled into this and made secure by sewing the peritoneal flap over it. The author has performed this operation fifty-three times without untoward complication or a fatality. It is his opinion that the large majority of abdominal disorders occur in that quarter of the population who have a congenitally ill supported colon. A timely colopexy will obviate the necessity of more serious subsequent operations.—*British Medical Journal*, December, 1931, ii 3701.

LEGAL

TERMINATION OF THE RELATIONSHIP BETWEEN PHYSICIAN AND PATIENT

By LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

Perplexing questions often arise in the practice of medicine as to when and under what circumstances a physician may safely terminate his relationship with his patient. In a general way, it may be said that a physician or surgeon having undertaken a case, whether medical or operative, in the absence of an agreement specifically limiting the services to be rendered is under a duty to continue to treat and attend a case so long as it requires attention.

In a very recent case in one of our Western States, the court had before it the question of the termination of the relationship between patient and physician. In summarizing the responsibility of the physician who had discontinued his attendance upon a patient, the court said:

"On engaging a physician to treat his case the patient impliedly engages him to attend throughout that illness, or until his services are dispensed with. The patient places himself in the hands of the physician and thereafter relies on the judgment and knowledge of the physician rather than on his own. A part of the correct treatment of the case is the careful and proper determination by the physician of the moment when the relation shall end. When a physician takes charge of a case and is employed to attend a patient, his employment as well as the relation of physician and patient, continues until ended by the consent of the parties or revoked by the dismissal of the physician, or until his services are no longer needed. For example, when a surgeon performs an operation, not only must he use reasonable and ordinary care and skill in its performance, but also in the subsequent treatment of the case. It is his duty to give the patient such attention after the operation as the necessity of the case demands, in the absence of any special agreement limiting the service or reasonable notice to the physician. It would seem that even before it is safe to discontinue medical treatment the relation of physician and patient may be terminated by a dismissal of the physician or by an agreement between the two to end the relation, or by the withdrawal of the physician after proper notice."

In a case in this State some years ago involving the question under consideration, the court charged the jury as follows:

"When a physician engages as here to attend a patient without limitation of time he cannot cease his visits, except—first, with the consent of the patient; or, secondly, upon giving the patient

timely notice so that he may employ another doctor; or, thirdly, when the condition of the patient is such as no longer to require medical treatment; and of that condition the physician must judge at his peril. Here it is not shown that the plaintiff was no longer in need of medical attention; so that the defendant had no right to discontinue his attendance, unless either the plaintiff consented or he gave her proper notice; and, if he left her without such consent or such notice, he was guilty of grave professional negligence. The defendant swears that, at his last visit, he notified the plaintiff that he was going out of town, and indicated to her a physician who would attend her in his stead. If this statement be true, the defendant's absence is excused and you must exonerate him from this imputation of neglect."

It becomes apparent from a reading of these cases that it is not always easy for a physician to decide just when and under what circumstances he may safely leave a case. Of course, if the patient by his own acts refuses to go on with the treatment, he cannot thereafter charge the physician with responsibility. In one of our appellate courts where an attempt was made to charge a physician with responsibility for failure to discover a fracture, it was said:

"* * * if the plaintiff prevented that (the rendition of certain admittedly proper treatment) by requesting the defendant to make no other visit, on account of the expense, until he was notified, the defendant could not properly be blamed for the omission to diligently look after the case."

In the case where the doctor wishes to withdraw from the treatment of a particular patient, the courts have clearly stated that he must give reasonable notice of his intention. What is reasonable notice is a question of fact in each particular case, and it is imperative that the physician exercise great caution before taking such a step. If, by the act of the physician in this respect, the patient be deprived of proper care, grave consequences may result. As has been aptly said by one of our courts: "A physician is never justified in withdrawing from a case he has once undertaken at a critical stage when his place cannot be supplied. To withdraw means voluntarily to refuse to continue his services. If he is ever justified in so withdrawing when it is apparent that to do so must result in injury it can only be where the patient obstinately refuses to follow the treatment prescribed. It is a fact honorable to the profession

that the question never seems to have been directly presented"

An analogous question is whether a doctor, having been called to attend a case, is entitled to continue to care for the patient in the absence of express request. A case in point was decided some years ago in this State where a doctor sued the husband of a patient to recover his fee, the physician having been first called by the husband to attend the woman during an illness and having continued to attend her throughout without further express authorization from the husband. There the court enunciated the following doctrine:

"* * * when a physician is employed to attend upon a sick person his employment continues while the sickness lasts and the relation of physician and patient continues unless it is put an end to by the assent of the parties or is revoked by the express dismissal of the physician"

The question presented when a physician temporarily leaves his practice has come before the courts. The established rule seems to be that if the physician notifies his patients he is going away and suggests a competent substitute in his stead, no neglect can be charged against him. However, here again a duty of care is upon the doctor, for if his conduct misleads a patient he may incur liability for unfortunate and unforeseen results.

This is illustrated by a case decided in New York in which the doctor had undertaken to treat a fractured arm, and informed the patient that he was going away for a brief period of ten days or two weeks. He gave her instructions as to the manner of caring for the injury in the meantime, and then failed to return for five weeks. The appellate court, in affirming a judgment against the said doctor, said:

"The defendant was called in as a surgeon in connection with a physician who was first summoned, who did not consider himself competent to treat a case of this kind and as such he undoubtedly undertook the case, and in doing so assumed to give it the care and attention required. If on this twelfth day of September he told the plaintiff he would return in ten days or two weeks and gave her instructions as to the course she should follow in the meantime and he failed to return for five weeks, and if in consequence of this failure to properly treat her during that interval this injury resulted, it would seem that the jury were justified in finding that the defendant was negligent in this particular. A physician who undertakes the treatment of a patient is bound to exercise not only the skill required but also care and attention in attending his patient until he notifies the patient that his professional relations are terminated."

ALLEGED NEGLIGENCE IN USE OF TOURNIQUET

A nurse came into the office of a doctor who specialized in orthopedic surgery, complaining of a stiff finger. She gave him a history to the effect that she had cut the finger some time before when a glass tube with which she had been giving a colonic irrigation had broken. The doctor found on examination the presence of the old scar and determined that the flexor tendon had been severed and was drawn up into the palm. He suggested an operation and she entered a hospital for the purpose. The doctor had her placed under a general anaesthesia and directed the nurse in charge of the operating room to place a rubber tourniquet on the left arm above the elbow in order that he might have a bloodless field for the operation. The skin of the finger was then cut, exposing the severed tendon, the opening being made from the point of laceration up through the palm so that the incision was about five inches long. He released the tendon and the end of it was drawn down and fastened to the stationary piece of tendon that remained in the girl's finger. The doctor then closed the wound with catgut, applied a splint and directed that the tourniquet be taken from the arm. About two hours after the operation the patient told the doctor she could

not move the other fingers of her hand, and that sensation had disappeared from the forearm and fingers. He immediately provided that she should be given treatments by a physiotherapist. She remained under his care for about two weeks and during that time sensation gradually returned to her arm and it gradually became normal.

The nurse thereafter brought a law suit against the doctor charging that due to the doctor's negligence she had suffered a paralysis of the left arm which persisted for about six months, and that she had incurred great expense for treatments to the arm. The claim was that the tourniquet had been either applied to the arm too tightly or that it remained on the arm for too long a period of time, and the pressure so applied to the blood vessels, nerves and muscles had caused a paralysis.

The case was brought on for trial before a judge, but without a jury, and at the close of the testimony introduced on behalf of the plaintiff the motion of the defendant to dismiss the complaint was granted. The court decided that there had been no evidence presented that the treatment on the part of the defendant was negligent or a departure from proper practice.

CLAIMED NEGLIGENCE IN TREATMENT OF SINUS TROUBLE

A young married woman consulted a specialist in ear, nose and throat cases with respect to sinus trouble that had been bothering her for some time.

The doctor examined her and diagnosed the case as an infection of the right maxillary sinus, and after keeping her under observation for a few weeks the doctor advised operative treatment. Under a local anæsthesia he punctured the nasal antrum wall with a Coakley trocar, releasing a considerable quantity of pus. Then with a saline solution he irrigated the antrum cavity. The patient returned daily for several weeks and on each occasion the doctor washed out the antrum which continued to show signs of pus. At the end of that time he advised the patient that he did not feel that washing the sinus through the small opening was effecting a cure and advised that she permit a more extensive opening of the antrum. The patient consented and the doctor again administered a local anæsthesia. He went in through the nostril and removed the anterior end of the inferior turbinate, making a larger opening in the naso-antral wall. This relieved the situation and enabled the doctor to wash out the pus. The patient returned for treat-

ment and observation occasionally thereafter for about two months. When he last saw her the difficulty was completely cleared up.

Some time later the doctor brought suit against the patient's husband in the Municipal Court of the City of New York to recover an unpaid balance of his bill for professional services. The husband interposed a defense, first claiming that the services rendered the patient were not rendered at his request and that he was not responsible for such liabilities as his wife might so incur, and further that the services rendered to his wife were negligently and unskillfully performed, by reason of which he demanded damages in the sum of \$1,000. The husband further claimed that the negligence and unskillfulness of the doctor had caused his wife to suffer great shock to her nervous system and subjected her to spasms of hysteria and crying.

After this defense contained in the counterclaim had been interposed, counsel for the doctor conferred with the attorney who had appeared for the patient's husband and pointed out that the counterclaim was wholly without merit, as a result of which the doctor's fee was paid in full and the case discontinued.

BROKEN NEEDLE

In this case the defendant doctor had been engaged to attend a patient during the delivery of her child. The doctor at the proper time delivered her of a normal child, and all went well during delivery and there were no tears. The doctor also removed the placenta and then proceeded to give the woman a 1 c.c. injection of pituitrin subcutaneously in the right thigh. Having scrubbed the spot on the thigh, he prepared to make the injection with a sterile syringe warning the patient not to move. The patient was conscious and replied that she would not move. However, just as the doctor inserted the needle under the skin and when he was about to press on the syringe, the patient twisted and jerked, and thereupon the needle broke and remained in the thigh. The doctor immediately informed the patient that the needle had broken off and made a superficial incision with a sterile scalpel in an attempt to remove the needle, but said attempt failed.

The same evening the doctor took the patient to the office of a radiologist who took an

x-ray picture of the woman's leg which showed the shadow of the needle. Thereupon, with the radiologist operating the fluoroscope, the doctor made a further attempt to remove the needle under local anesthesia but was unsuccessful in doing so. He immediately dressed the wound and returned the patient to her home in an ambulance. The doctor thereafter attended her for several weeks, at the end of which time the wound had healed although the needle remained embedded in the thigh.

An action was subsequently instituted by the patient, claiming that due to the negligence of the defendant in causing the hypodermic needle to break and remain in the plaintiff's body she had been severely injured and had suffered great pain. The case was tried before a judge without a jury, and at the close of all the testimony the court directed a verdict in favor of the defendant doctor, thereby ruling that the mere fact of the needle break did not impose liability upon the doctor and that the plaintiff's testimony had failed to show any negligence on his part.

HOUSE OF DELEGATES

MINUTES OF SPECIAL MEETING

The Special Meeting of the House of Delegates of the Medical Society of the State of New York was held at the Ten Eyck Hotel, Albany on Thursday, January 14, 1932, at 2:15 P.M.

Dr. John A. Card, Speaker.

Dr. Daniel S. Dougherty, Secretary.

1. OBJECT OF MEETING

The Speaker: As you know you are assembled here today in Special Session under the resolution passed by the House of Delegates, June 1, 1931, to consider the report of the Joint Committee who were authorized to study the report of the Governor's Special Health Commission, that is the only business that will be transacted at this Session.

Will the Secretary please call the roll?

2. ROLL CALL

The Secretary: The Assistant Secretary will kindly call the roll.

The Assistant Secretary called the roll and the following delegates responded:

Frederic C. Conway, William P. Howard, Lyman C. Lewis, J. Lewis Amster, Frederick L. Flynn, Edward R. Cumiffe, Louis A. Friedman, Vincent S. Hayward, Jacob A. Keller, Edward C. Podvin, Frank M. Dyer, Joseph P. Garen, George W. Cottis, Earl W. Wilcox, Anton S. Schneider, C. Knight Deyo, William A. Krieger, Aaron Sobel, John D. Bonnar, Baldwin Mann, Albert A. Gartner, Mary J. Kazmierczak, Charles Leone, Edward J. Lyons, Milton G. Potter, Charles C. Trembley, Peter J. Di Natale, William M. Rapp, Norman L. Hawkins, E. Jefferson Browder, Frederic E. Elliott, Walter D. Ludlum, Harold R. Merwarth, F. Edward Jones, Lynn B. Chase, William A. MacVay, Clarence V. Costello, Floyd S. Winslow, Horace M. Hicks, Everett C. Jessup, Benjamin R. Allison, Emily D. Barringer, Edward M. Colie, Jr., C. Ward Crampton, Edward V. Denneen, John V. Donnet, TenEyck Elmendorf, B. Wallace Hamilton, David J. Kaliski, Samuel M. Kaufman, Frederick C. Keller, Samuel J. Kopetzky, George W. Kosmak, Arnold Messing, William M. Patterson, Alfred C. Prentice, Nathan Ratnoff, Morris Rosenthal, Newton T. Saxl, James W. Smith, Terry M. Townsend, Franklin Welker, Frederick J. Schnell, Richard H. Sherwood, Charles D. Quinn, Hyzer W. Jones, Thomas P. Farmer, Frederick H. Flaherty, Homer J. Knickerbocker, Floyd J. Atwell, Carl Boettiger, James R. Reuling, Jr., Albert L. Voltz, Augustus J. Hambrook, George A. Leitner, Stanley W. Sayer, George S. Towne, Dudley R. Kathan, William C. Treder, David W. Beard, Leon M. Kysor, Herbert B. Smith, Arthur T. Davis, Frank S. Child, Luther C. Payne, Morris Maslon, Walter S. Bennett, Lucius H. Smith, Harrison Betts, Merwin E. Marsland, Romeo Roberto.

The following Officers and Chairmen of Standing Committees were present:

William D. Johnson, Charles G. Heyd, William H. Ross, Charles C. Trembley, Harrison Betts, Daniel S. Dougherty, Peter Irving, Frederic E. Sonder, John A. Card, George W. Cottis, James F. Rooney, Arthur W. Booth, Harry R. Trick, Arthur J. Bedell, Thomas P. Farmer, Harry Aranow, Charles H. Goodrich, Herbert A. Smith, James E. Sadlier, Louis A. Van Kleeck, Herbert L. Odell, Augustus B. Santry, E. Carlton Foster.

The following ex-Presidents were present:

Charles Stover, James F. Rooney, Arthur W. Booth,

James E. Sadlier, Harry R. Trick, James N. Vander Veer.

The Speaker: There being a quorum present, I will declare the House in session to consider the report of the Joint Committee which has been studying the preliminary report of the Governor's Health Commission, and I desire to say at this time that the members of the Joint Committee who are not members of the House of Delegates, are accorded the privilege of the House today.

The Secretary: With the exception of voting.

The Speaker: I declare that members of the Committee are welcome to participate in the deliberations of this session but without vote.

3. REPORT OF THE JOINT COMMITTEE

Dr. Ludlum of Kings: All of us present are here because we have read this report with considerable care, and I think that we all feel that this Joint Committee has done a very large amount of very satisfactory and efficient work.

We would all use different words in expressing the same thought, but so far as I can see the recommendations and expressions of opinion are very satisfactory. And I should like to offer the following resolution:

That the report of the Joint Committee be received and that the recommendations and expressions of opinion therein contained be accepted as recommendations and expressions of opinion of the House of Delegates of the Medical Society of the State of New York.

The Secretary: I would like to call attention to the fact that there is nothing before the House, the Committee has not reported to the House.

The Speaker: I was about to rule that the motion of Dr. Ludlum was not in order, because there is no report before the House.

The Secretary: I move, therefore, that the report of this Committee be considered before the House as printed and received by the Delegates and the County Societies.

Motion seconded.

The Speaker: I am going to declare that motion out of order at the present time, and I am going to ask Dr. Farmer, the Chairman of the Joint Committee, if he will present the report.

Dr. Farmer: On behalf of the Joint Committee appointed by the House of Delegates at its meeting in Syracuse in June to study the report of the Governor's Special Health Commission and to make recommendations to the House of Delegates I submit the report as sent to the Secretary of the House of Delegates and published in the official organ of the Medical Society of the State of New York, the NEW YORK STATE JOURNAL OF MEDICINE, in the issue of January first, 1932, page 29, and move that it be received by the House of Delegates for action.

The Speaker: The report is now before you.

Dr. Ludlum: Is my motion now in order?

The Speaker: I will rule on it if you will state it.

Dr. Rooney: I rise to a point or order. My conception of this matter of receiving a report is that, receiving a report is tantamount to acceptance of that report and making it a body resolution of this House.

I therefore, ask the Chair to so rule, that the House may understand that question, and may not by voting to receive the report, place itself in a position of adopting it.

The Speaker: You did adopt it when you received it.

Dr. Rooney: A point of order, I withdraw my request

and ask unanimous consent to speak in relation to the adoption of this report.

Motion seconded.

The Speaker: The motion is made for unanimous consent to consider the adoption of the report.

As there is no objection, it is so ordered.

Dr. Rooney: The only way that this matter can be changed now is by a motion to reconsider.

The Speaker: You are right.

Dr. Rooney: And that motion to reconsider must come from someone who voted in the affirmative on the preceding motion. Not having voted I desire to call the attention of the House to the necessary procedure in order that if the House so desires to change its opinion that the proper motion may be made.

Dr. Kobetzky: I move the reconsideration of the acceptance of that report, I having voted in the affirmative.

Motion seconded.

The Speaker: The motion is before you to reconsider the acceptance of the report.

All of those in favor signify by saying aye; contrary minded, no. It seems to be and is carried. So ordered.

Dr. Rooney: I move that the House proceed to the consideration of the report.

Motion seconded.

The Speaker: The motion is made and seconded that the House proceed to the consideration of the report.

The Secretary: We have reconsidered our action. The original motion is now before us, that the report be accepted.

Dr. Rooney: I move that in place of the word "acceptance" that the words used be that "this House will proceed to the consideration of the report of the Joint Committee."

The Speaker: The motion is amended and now reads that the House shall proceed to the consideration of the report of the Joint Committee.

Are there any remarks?

All those in favor signify by saying aye; contrary minded, no.

Dr. Rooney: That is not my amendment, my amendment is that the word "accept" be deleted from the original motion and that there be substituted the words "that the House will proceed to the consideration of the report of the Joint Committee."

Dr. Farmer: I want to correct Dr. Rooney. I made the original motion and the wording was "received." So we strike out the word "received" instead of striking out the word "accepted."

The Speaker: I have had my attention called to Roberts' Rule of Order, and I wish to quote from paragraph 53 which I think will clarify the entire situation. "A very common error is after a report has been read to move that it be received, whereas the fact that it has been read shows that it has already been received by the assembly."

The Speaker: There is a motion before the House, that this report be considered by the House of Delegates.

All those in favor signify by saying aye; contrary minded, no. So ordered.

Motion as amended was carried.

Dr. Ludlum: May I ask if my motion is now in order?

The Speaker: Please repeat it, Dr. Ludlum?

Dr. Ludlum: I move you, sir, that the recommendations and expressions of opinion contained in the report of the Joint Committee be accepted as the recommendations and expressions of opinion of the Medical Society of the State of New York.

Motion seconded.

The Speaker: You have heard the motion. Are there any remarks?

Dr. Rooney: I hope that this body will not adopt such a procedure as is proposed in the motion of Dr. Ludlum. This report contains too many controversial matters upon which there may be a very great difference of

opinion and should not be disposed of by any such blanket procedure as is proposed.

I hope that the House will take up the separate sections and the separate recommendations one by one.

Dr. Bonnar: I wish to oppose that motion. Inasmuch as we are assembled here for the purpose of considering this report in detail, I take the privilege of moving as an amendment to this motion of Dr. Ludlum that we consider the report of the Joint Committee section by section.

The Speaker: That would be equivalent to a substitute motion, and I will receive it as a substitute motion and not as an amendment.

The Speaker: Dr. Bonnar, is the substance of your motion that the House consider the report section by section and adopt or reject it section by section?

Dr. Bonnar: That is the substance of my motion.

The Speaker: All of those in favor signify by saying aye; contrary minded, no. It is so ordered.

The substitute motion was carried.

The Speaker: The report is before you for consideration.

4. COUNTY HEALTH UNITS

Dr. Goodrich: The first definite recommendation of the Joint Committee is contained on page 31, the upper half of column two of its report printed in the January first Journal; and in relation to that I would offer the following resolution:

Resolved that while recognizing that the principle of County Health Units is ultimately desirable, the House of Delegates record its opinion that the mandatory provision for the same be deferred. (The vote—see Section 10.)

Resolution seconded.

The Speaker: The resolution is now before you for discussion.

Dr. Rooney: I can see no reason for this motion. Any county, under the permissive section of the present law, that desires to have a county health unit can so constitute it. The proper subject of discussion here is the question of the mandatory provision.

Are we in favor of any sort of mandatory provision now or in the future, if not why use the word "deferred?" Why not state that we are opposed to the mandatory provision, because under the present law, any county health unit if it so desires by its own action, and through its own elected boards may constitute that health unit just as has been done in Westchester County.

Now, why temporize with this thing. Why play with it? We can lose nothing by standing straight-forwardly for what we believe.

Let us be honest enough to advise the public, as we are by law required to do, that in our opinion all mandatory provisions that will lead ultimately to the complete centralization of authority in state and national government are begun in just this way.

If you want that, vote for this "deferred." If you don't want it, let us state that under the present law any county desiring a county health unit may so constitute, and that we see no reason for any mandatory provisions in the law whatsoever.

I move you, therefore, to amend Dr. Goodrich's resolution by striking out the word "deferred" and adding the word "because." May we have the resolution repeated so we may have the exact wording.

The Speaker: I will ask the Secretary to read it.

The Assistant Secretary: "Resolved that while recognizing that the principle of county health units is ultimately desirable, the House of Delegates record its opinion that the mandatory provision for the same be deferred."

5. MANDATORY ESTABLISHMENT OF COUNTY UNITS

Dr. Rooney: I move to substitute.

Resolved that the Medical Society of the State of New York, realizing that in certain instances the institution of County Health units may be desirable, has no objec-

tion to this portion of the report with the proviso however, that such be inaugurated and controlled by local government as already provided under the present Public Health Law (The vote, Section 11)

The Speaker Dr Goodrich will you second that motion

Dr Goodrich No, I want to speak in opposition to it Motion seconded

The Speaker The motion is made and seconded

Dr Goodrich My reason for presenting this resolution was merely to place before you in brief words what the committee said in its very ample report

I believe that we have had at work on this report a combination of two of the strongest and brainiest Committees that we possess in the State Society

They have met many times and in many places and have considered every angle of this question and I feel that their wisdom is much greater than mine in regard to this and am willing to support their recommendations because they know what the ground looks like They know that in all probability the county health unit will ultimately be passed as a law a mandatory law, that our refusing at this time to consider such a thing would mean that we were disposed of as an opposing element

But if we vote that it be deferred we will probably be considered If the vote is defeated, we will probably not be considered

I believe there is a very good reason why the original resolution should be passed in order to give us time to educate those who need education along this line

Dr Aranow As far as the passing of the law is concerned I don't think there is any fear any law will be passed this year that will make anything mandatory that involves extensive expense

The point I want to bring up here is this Whether we accept Dr Goodrich's resolution or the amendment we are not giving it consideration We are simply passing one resolution or another

I would like to hear arguments for and against concerning argument why we should or why we should not accept the report

The Speaker Is there any further discussion on the substitute motion?

Dr Knickerbocker Conditions vary in different parts of the state That you must concede What may be fine for Westchester may be absolutely impossible for Ontario Until it can be definitely proven that a county health unit is the proper thing to have it should not be made mandatory

We are getting too much mandatory legislation in general We people of the State feel that we are having our constitutional rights constantly undermined and taken from us by mandatory legislation at our expense

For instance, the night before last our County Medical Society took this matter up and deferred action on it because we felt that it was not urgent and that we wanted time to have more study We felt that the two cities in our county the population of the county a mandatory law and they would go on and administer their public health work as they have always as home rule It may cost a little more to do that but we at least have the satisfaction of doing it ourselves and paying the bills

The people in the county outside of these two cities have foisted upon them or would have foisted upon them by this legislation should it pass, an expensive far flung inefficient administration which at the present time is very well taken care of by the local people This proposition is not universally applicable and is against the interests of any county desiring to maintain its own government and home rule

Dr Bonnar The word 'mandatory' is I think obnoxious to every citizen We are a nation of liberals We expect to preserve that relationship to our citizens Liberty liberty is the basis upon which the Govern-

ment of this country is founded, and to have mandatory legislation imposed upon us is highly obnoxious and censurable

Now, to make this mandatory would require legislative procedure.

Dr Goodrich The original resolution says the mandatory feature shall be deferred, and the substitute resolution says that it shall be disapproved, am I correct?

The Speaker You are

Dr Goodrich So no motion is in favor of it under the conditions and the discussion against it is unnecessary

The Speaker I shall have to rule that Dr Bonnar is in order because the Report does say that they believe that it should be mandatory Continue Dr Bonnar

Dr Bonnar What I said before is that mandatory is obnoxious to a liberty-loving people The liberty to do what we want to do, with what we have to do it with is of course fundamental and to take away the foundation is to allow the superstructure to fall

Now, what is wrong in essence my friends can never be made right in substance What is wrong in principle can never be made right in practice And therefore 'mandatory' means to command to obey Home rule is an established virtue in our form of government and mandatory is not established but it is being fostered to gain certain rights certain powers, certain authorities which in their very essence are obnoxious

I hope that this sentiment will prevail because it is the American form of Government from the bottom, from the people, not from some person above, who would control us

The whole object of this procedure is to gain power at the expense of liberty Therefore, I am opposed to it

Dr Davis I think I could point out, the reason for mandatory You have to have a health department now, according to law and to have it in every town village and city in the State

Dr Aranow May I have the floor again?

The Speaker Yes, sir

Dr Aranow I want to speak not so much as a Delegate but as the Chairman of the State Legislative Committee

I am sure the Governor and his Committee meant well when they tried to study out the problem, and while this Society may be opposed to the mandatory provision, I would like to word it in a way that will not hurt the feelings of the men who earnestly made an effort to change or do things for the betterment of the State of New York And if the Speaker would be kind enough to read Dr Goodrich's original motion again, I will try to substitute a motion

The Speaker There is a substitute motion before you now

Dr Aranow I want to see whether I can make a substitute motion that will be more acceptable without hurting the feelings of the people who tried to do this work

The Speaker You want the original motion read for your information is that right?

Dr Aranow Yes, sir

The Speaker The Secretary will please read the resolution of Dr Goodrich

Assistant Secretary Resolved that while recognizing that the principle of the county health unit is ultimately desirable the House of Delegates record its opinion that the mandatory provision for the same be deferred

Dr Aranow I will accept the first part of the motion which is practically an approval of the principle and substitute for the last phrase the words, "that the House of Delegates is opposed to the mandatory provision as being impractical and unnecessary"

The Speaker Inasmuch as that motion does not contain any new matter, I will have to rule that it is out of order The substitute motion is before you Is there any further discussion?

Dr Podvin I would like to call attention to Dr Aranow's first suggestion Those of us particularly

from New York City where legislation of this kind does not prevail, have no intelligent idea upon what to vote, would it be possible to have a member of the Committee or the Chairman of the Committee give us the reasons why the recommendation as read by Dr. Goodrich was presented to this House?

I believe there must be good argument on both sides. We outside of the area affected want to vote intelligently on the subject.

The Speaker: I will be very glad to afford Dr. Farmer the privilege of the floor.

6. STUDY OF REPORT BY THE JOINT COMMITTEE

Dr. Farmer: The Joint Committee held meetings at various places throughout the State so that it might be convenient for every County Medical Society to have its authorized representative appear before the Committee.

Every County Medical Society was given ample notification not only of one meeting but of several meetings, so that if for any reason the representative could not appear at one time he could appear at another time.

Furthermore, the Committee invited the Commissioner of Health of every County Department of Health in the State to appear before it, and interrogated him on every vital point that they could think of. They also asked other persons who might have had some information to come before the Committee and give their information.

The Committee approached this whole subject without any pre-conceived opinion whatsoever. It was only after we had gone through our records and tabulated the advantages and the objections as detailed in our printed report that we made up our minds as to how we should report.

I am quite in agreement with Dr. Knickerbocker that the conditions vary very greatly throughout the State, but I do feel that this opportunity should not pass without criticizing one of the County Societies because of the fact that their representative told us that he did not know what the Governor's Health Commission's report was about, nor did he know for what purpose our Committee was appointed.

Now, where can a Committee get to when they get such help? I think that ought to be brought out here.

We met that situation in other cases. On the other hand, I am sure if you men could have had the privilege which we had of going through the State and finding the energetic, progressive men who took occasion at great time and expense to come before our Committee and report honest and conscientious objections to this plan, or give splendid arguments in favor of it, you would have been inspired with what the medical profession really means as a public health agency.

Now, we found to begin with, that the State Society was on record as favoring County Health Departments. There was no debate about it. The Medical Society of the State of New York, I believe, at its meeting in Niagara Falls approved of the principle of the County Health Department. So that part we have to accept unless we reconsider our previous action.

We felt that the arguments for a County Health Department certainly were progressive ones. We cannot stand still in this matter any more than we can stand still in the matter of the practice of medicine.

Just as the Governor said, new things in medical science and new things in public health administration are coming up every day, and it is simply absurd to think that all things can be accomplished in the old method of procedure. Everybody knows that. We don't need to debate it. The old procedure possibly can be carried on better under the old plan. But there is no question about the fact, in order to go along with the progress of medicine, we do have to change our plans from time to time.

Furthermore, it struck us that the medical profession of the State of New York was a very vital force in any progress that was to be made in public health, and with-

out its complete coordinated cooperation, the public would not receive the benefits that they should receive.

Whenever the Joint Committee advocated a County Health Department, we always meant a properly organized County Health Department. We meant one that was organized within the county, that exemplifies the spirit of home rule better than the present practice of health administration in counties now does, and the sort of a department that would give opportunity for coordinated cooperation on the part of the medical profession of that county to take part in public health work.

Now, we found out that there was a great realization of this fact by the Medical Societies as represented by their delegates to our meetings and furthermore there were several counties that wanted us to approve of the mandatory provision at the present time.

I feel that we cannot stand in absolute opposition to the question of mandatory provision as Dr. Rooney or Dr. Bonnar have indicated. Mandatory laws are very, very common. And in the question of public health, as you know, the rights of the State are quite paramount. That goes back to the time of Disraeli who made the statement that the first duty of the State was the care of the public health.

We don't want to come to the point when it will be necessary for mandatory action. Our Committee feels that there is enough expression throughout the State of realization of the progress that can be made by a county health organization, originating where it should originate, in the medical profession of the State. If ample time is given there will be no need for a mandatory provision, and then, perhaps, if there are a few laggard counties where the governing body of the county is an obstacle to this thing, this Society will want a mandatory provision. It will be the only way of improving conditions. I personally feel that the mandatory provision at the present time is unwise.

I am not trying to cater to any one part of the State Society. I feel that every member of the Committee has approached or arrived at his decision in the same way. We are trying to do the absolutely right thing. To create a mandatory department of health at the present time, in such short time, is unwise, because there will not be the right type of a County Health Department. We must obtain the proper men to act as the commissioners of health, men who are properly trained. We believe that local men should be trained for these positions. We believe there should be local initiative and local control, and I am sure when those things are all done nobody is going to have any objection to a County Health Department.

And then when two or three laggard counties refuse to do this—I don't mean the medical profession, but the political governing body, and if the medical officers in those counties are unable to succeed in having a County Health Department organized, then our State Medical Society is going to reverse itself and demand mandatory provision.

Dr. Flynn: I think we are getting very much excited over a political measure. The creation of a county health position in the Constitution of the State of New York—The Constitution of the State of New York will take care of that. Why should we fuss about a political proposition for the creation of more jobs? That is what it amounts to. And to put the thing down as being approved by the Medical Society and made a mandatory provision as Dr. Rooney has stated is one of the worst precedents that we could establish.

Health Commissioners, Deputy Health Commissioners, and so forth, are nothing more or less than political positions, and it is pretty near time we realized that. This is a taxpayer's argument. It has nothing to do with the medical profession. It is a political measure, and the Medical Society of the State of New York is being used as a goat.

Dr. Podvin: Regardless of the economics of the question I want to call attention to one point which has not

been mentioned; namely, that it is going to facilitate and make easier the administration of state aid to counties from which they will derive benefits that they cannot have without it, and state aid cannot be properly administered unless you have a unit with which to deal.

Dr. Knickerbocker: I rise to a point of information. Does Dr. Farmer know that the representative from the County who gave such an unsatisfactory report was unaware of his appointment within three days prior to his appearance in Syracuse and had no data on which to express any opinion?

Dr. Farmer: We have no criticism of the man himself, but we are criticizing the County Medical Society, which did not see fit to appoint a man who was versed on the subject. The County Medical Societies knew all about this from the June meeting. They had plenty of time to see that their representative was prepared. Letters had been sent to the Secretaries of the County Societies in June or July. It isn't the representative but the County Medical Society which is dilatory.

Dr. Sadler: I wish that it were possible for every man present in this audience, even though he represents his particular county society, to read that set of volumes which represent the stenotype report of the meetings of your Joint Committee, and I feel that if you were conversant with the report of the Governor's Special Health Commission, and also as conversant as you would be with the medical opinion throughout this State, you might consider that the report of your Committee which asked for deferment of the mandatory principle was rather mild.

Now, to speak more particularly on the report of the Committee, the Joint Committee has had in mind only a county health unit which would be efficient, economical and progressive, an organization which through the co-operation of a medical profession should benefit the community and the medical profession.

The Joint Committee does not feel that establishing county boards of health without regard to standards is a progressive step.

I am not going to dilate upon the number of meetings we have held throughout the State, but I am going to, as a member of that Committee, thank the hundreds of men who gave up their time to come and express their opinions before the Committee.

With reference to the question of State control, centralization, I wish you gentlemen would study it. You gentlemen who fear that this means centralization in the State Office Building, I wish you could have heard the testimony delivered with reference to three departments of health now in existence in New York State. There never could be a finer argument on decentralization of power than is expressed in those volumes by the records of three county departments of health in this State, nor could there be a better establishment of the fact that the County Department of Health is actually a home rule principle.

With reference to the fourth county department of health—I think the least said the better, but it would seem to me personally, that it represents what a county department of health should not be.

We gave this matter very careful painstaking consideration. There are five counties in this State, all of them counties of a great deal of importance, that are definitely in favor and so expressed themselves, of the mandatory procedure. There is a fairly considerable number of counties—I cannot give you the exact number—that are working out at the present time a very nice cooperative coordinate arrangement with their various health organizations and governmental forces in their efforts to establish county departments of health under the permissive plan, under the permissive law, and they are getting along very nicely.

Eight counties in the State did not take interest enough in the work of the Joint Committee or in the whole question to even send a representative.

A fairly considerable number of county societies were against the mandatory procedure.

Your Committee was quite impressed by the splendid activities being carried on, especially in two of the county departments of health, Suffolk and Cortland, where, without the use of clinics, with the doctor being made paramount in all health matters, a splendid principle of home rule is being carried on.

Westchester County rather stands by itself, a splendid department of health, the department of health in a very rich county, and as we all know, these departments of health whenever established will vary to a very considerable degree, depending upon the wealth and prosperity of the county.

Your Committee also feels and one reason why it asked for deferment of the mandatory procedure, is because the recently enacted welfare law constitutes a fairly considerable burden upon the taxpayers, and I think we are all cognizant of the fact that it has not been properly and sufficiently digested as yet by the government authorities in the county or by the taxpayers. We were also cognizant of the fact that the old age pension law carries with it a large volume of expense, and that it in turn has not as yet been digested by the taxpayer and the governmental forces. We are also cognizant of the fact that this is a period of great economic depression, and therefore, that the taxpayer should not be additionally burdened.

Furthermore, we have had a very considerable amount of sympathy for the counties that are trying to work this out under the permissive plan, and that are on the verge of going over.

Furthermore, or rather, for some of those reasons, we felt that the mandatory provision should be deferred.

But, gentlemen, how many laws are passed up on this hill each year that are not mandatory? Very few. And at the present time, as was told you by Dr. Davis of Suffolk, you are working under a public health law that is mandatory.

I also feel, that you are spending several thousands of dollars each year for a Public Relations Committee, of which you did me the honor to make me chairman. Of what use is your Public Relations Committee, I ask you, if it is placed in the position of objecting to everything that is progressive or anything like this which is progressive in medicine? It would seem to me that a proper coordination, a proper cooperation between the governmental forces, both state and county, with your Public Relations Committee and your Public Health Committee, and with the lay organizations during this deferred period, should be the proper line of activity, and it would seem to me that you should adopt this principle of deferment of the mandatory principle and instruct your Public Health Committee, as this report says, and perhaps your Public Relations Committee, if you so choose, to work this out from an educational standpoint, not only with the medical men but with the people of the State, and have this brought to a point where it could be put over amicably county by county.

7. PRINCIPLE OF MANDATION

Dr. Rooney: I would like to say a few words in relation to my substitute motion (Sec. 5). All the arguments that I have heard against it have been purely emotional ones leading toward the question, does the House give a vote of confidence to its committee which is perfectly correct.

I have heard the same type of argument in relation to mandatory provisions advanced, the same idea of inevitability, the same idea of joining the progressive group, the same idea of not taking too definite a position. All of these arguments are old ones to me. I have heard them since 1917 in relation to everything that has been advanced in relation to medicine joining a so-called progressive movement.

If the movements are progressive the argument is

valid. The essential question is: Are these movements actually progressive? Or, are they very much like the old Irishman's maxim that "far away cows have long horns?"

I feel that the policy of this Association has been against mandation. Irrespective of all of the arguments that I have heard advanced I am still of that opinion. I have yet to hear a valid financial or professional argument advanced by any of the speakers for their side of the question to merely defer the idea of mandation.

Now, there is a very definite argument that is a public one, and that is the question of finance. In Albany County a careful estimate of what the cost to the taxpayers of this county in the event of the compulsory institution of a county health unit would be, has been that the total expense at a minimum figure would be two and one-half times the present amount expended for all health endeavors that are going on in the county.

I realize that we are not spending perhaps as much money for public health as we should. On the other hand, a serious question to the taxpayer today, in view of our present situation, is that one thing.

Has the State Government the right to impose upon the individual smaller federation a mandatory policy that is going to require them to tax their own taxpayers for benefits that so far as I have been able to see from a reasonable study of this question are perhaps illusion, except in so far as centralization of power is concerned.

I don't pretend to have been all over this State as the Committee has, I have no criticism to offer, I have nothing but commendation for the labors of this Committee. But irrespective of those labors, I feel that the question of mandation is important and that the Society should make up its mind regarding it. It makes a beginning for more and more unnecessary legislation. It is leaving the door partly open. Leave the door partly open; start an institution. Next year amend it a little. When the compulsory health advocates could not agree on total compulsory health they said: We will make it permissive. Then try it out and amend it each year until it is finally complete and compulsory.

I have heard these same arguments for years. I still hold and I still feel that there is a little over a half of the population of this State which will be affected by this law. All of Greater New York will not be affected. New York City is extremely wise. From the very beginning they have created a state within a state. There is no section of this State that has as much local self-government as New York City. There is no state in the Union in which statute after statute passed by the Legislature for the whole state reads "Except for the Greater City of New York." The proposed law relates to all of the State except that of the Greater City. Now, then, New York County has no stake in this thing. Greater New York has no stake in this thing. Kings County has no stake in this thing. But the counties outside of Greater New York have a manifest and a great stake in it. And it is from those representatives that we should hear the main arguments.

I feel that this matter should still remain one of education, as the present law provides permissive action by counties, the refusal to the Commission for centralization in the Health Department by the prescription of qualifications for officers under the proposed act, and when any central department is given the right to prescribe the qualifications for those who will administer the law they hold every official that qualifies under those qualifications in their hands, and I will call your attention to the repeated enactment of the State Society of Sanitary Officers, which is not controlled entirely by the Health Department, but which repeatedly has been in effect controlled by it.

I do not intend to take up your time any further. I hope that this House without offense to anyone, and I intend no offense to anyone, State officials, the Governor, his Welfare Commission, or members of this Committee,

were all in my opinion very largely well-meaning but not entirely guided by the medical profession,—the number on that Commission of actual practicing physicians was very few—I hope that this body will have the courage to stand up for its convictions and not vote for mandation either now or in the future.

Dr. Colic: It is perfectly true as the last speaker said that New York County and the other counties of the Greater City are outside of this consideration, but the physicians resident in the Greater City are citizens of the State of New York, and nothing which is a real issue to the profession is foreign to their interests. I think as the gentleman from Erie said that the idea of superimposed and mandatory government is obnoxious. One of the great reasons is the tremendous tendency of democratic institutions as they have been working out with us to degenerate into government by regulation and this is another indication of the same thing. I think we have got to fight mandation.

Dr. Garen: Is it in order for me to offer a substitute resolution upon the substitute resolution?

The Speaker: State it, and I will rule on it.

Dr. Garen: Resolved that the House of Delegates following consideration of the report of its Joint Committee hereby records itself as opposed to universal compulsory county health units.

Motion seconded.

The Speaker: I think I shall have to rule that at this time that is not in order, because it contains entirely new matter which is not relevant to the question at hand regarding the report of the Special Commission. I think it would be relevant at another time but not just now.

8. CONTROL BY COUNTY MEDICAL SOCIETY

Dr. Cottis: I agree very largely with something that almost every speaker has said, especially agreeing with Dr. Rooney.

This is not a matter for emotionalism, and I think it is not a matter for politics. I think it is a very serious matter that this House should consider this question in the same way that its Joint Committee has, purely from the point of view of the good of the profession and its relations to the public.

I am in a peculiar situation in that I know more than anybody in this room all the circumstances that lead up to the recommendations of the Governor's Commission.

I shall try not to be emotional nor feel emotional.

The first thing that I want to impress upon you is this: That that Commission did not have a great representation from the practicing physicians of this State. Dr. Ross and I were the only ones, I think, who did practice medicine for a living.

And yet that Commission met for a whole year and considered some 15 or 16 divisions of public health, appointed sub-committees, so that we had something like 85 people working on the Commission, of whom about 55 were physicians, before anybody even suggested the idea of a county board of health. The Milbank Foundation, the State Charities Aid, did not propose this thing. It was only after we had our Sub-Committees' reports on the various things that were necessary that it occurred to me that all of these things that had been discussed, the question of the school child, of cancer control, venereal disease control, tuberculosis, nursing, and the thousand and one things that now go into public health, that all of the recommendations made by these Sub-Committees were futile because there was no machinery for carrying any of them out.

Now I will emphasize this; That I or Dr. Ross—I am not sure which, was the one who called the Commission's attention to the need for some machinery by which this thing could be carried out under medical supervision. Make no mistake about that. That did not come from the lay organizations. That came from one of us two medical representatives.

Now, I will tell you why. There has been a good deal

of loose talk about mandation, mandatory rule, rule from higher up. Don't you realize that all through this State today, in every county in the State most of the public health activities are being carried on by county-wide organizations which are essentially lay organizations? We have our Tuberculosis Association in every county who employ nurses and send them around. We have our school nurses. We have our social welfare worker. We have our dependent children organizations. The whole State is being administered from the public health point of view today by voluntary lay organizations in every county, with no supervision of any reputable qualified organization in that county.

Now, the reason that we proposed that what this Society decided two years ago was a good thing, the County Organization of Public Health should be made mandatory, was simply that if it is good the only way you can make it effective is by substituting one mandate for another. At the present time it is mandatory that the medical profession shall have nothing to say about rural boards of health, because the present law provides that every Town Board of Health shall be made up of the town trustees and unless the local doctor wants to run in politics and become a trustee of the town he cannot serve on that Board of Health. The medical profession is not recognized and has nothing to say about it at the present time.

We talk about State supervision. Every health officer in this State today is under the supervision of the State sanitary inspector appointed by Albany without anything from us in regard to approval or disapproval. We propose to take that power away from Albany and bring it home to our little local communities. We propose to take this mandate away from the towns and villages and center it in the county so that a county board of health appointed by our own county Supervisors with at least three men on that Board nominated by the County Medical Society should have the power to tell these lay organizations, these tuberculosis nurses, and school nurses, and all the rest of them what they shall do.

In other words, gentlemen, this is the first time in the history of this State that a law has been proposed which compels the County Medical Society to be recognized in public health matters.

In regard to these two motions, I think the first motion is preferable simply for this reason: On account of the financial situation, on account of the fact that there is opposition in some of the counties in the State, it would be very unwise to have a bill pass the Legislature this year compelling every county to have a county board of health. The Commission itself feels that it would be unwise. We feel that there is not the personnel developed yet to supply local men for this work, and we think every county ought to have its own man ready for the work when the work comes.

Therefore, I am heartily in agreement with the recommendations of this Committee, and I want you to notice that that Committee has studied this thing and that they are not advocates of State medicine. They are some of the old stalwarts in this State Medical Society. They have always worked for organized medicine. Whatever you may say about Dr. Ross and myself, that we have sold out in the hopes of some day riding in a State limousine, you may believe that if you wish, but you can't believe that of this Committee. Therefore, I think we should endorse the recommendations of this Committee to the extent of advocating a local county form of medical government under the control of the County Medical Society, as this would be, and not close the door, as Dr. Rooney would have us do to advocate that this thing be made statewide at some future time. If we have five or six counties voluntarily taking this up next year, and it seems as though we will, if the thing can be demonstrated, as it has been demonstrated in three counties of the State already, as it has been demonstrated in every county of the State of Ohio for twelve years,

the time will come when we are all going to be convinced that this thing is worthwhile. There may be a few counties where the politicians will not allow it to go over. Then we may want to make it mandatory in order to have the rest fall in line. If we adopt the substitute motion we are not only closing the door to that sort of thing, but we are making it very hard for us as a Society perhaps five years from now to demand that what we have by that time recognized as the best form of rural health administration, should be made mandatory. We are not advocating a new mandate. We are advocating a change of a mandate from the little towns and villages where everybody must pay fifteen cents per head for the town health officer, whether he wants to or not, to the County Health Board which should be done now.

I want you to consider whether the first motion does not meet the situation, leaving it indefinite, reaffirming what this Society did two years ago, in saying that this is the logical way to take care of public health in the rural county and deferring indefinitely the mandatory provision until such time as we are convinced that we want it.

9. MANDATION VS. PERMISSION

Dr. Ross: I suppose that I have been in the limelight enough during the last year to claim the privilege of talking to you for a few moments, and if I indicate some personal history in addition to discussing the Governor's Health Commission, it will be because I think that I have a right to do so.

Last year as President of the State Society I undertook to discuss the situation in medicine between public interest in organization for the distribution of medical service, on one hand, and the physician's worry about his economic security, on the other. I made an effort to advance the principles of constructive medical relationships as a means of solving this problem. I found it harder work than if I had just kept to the middle of the stream. It is always harder to advocate something than to talk against something because it is harder to construct than to destroy.

Last year I had to assume a position of leadership. This year I have the freedom of the ranks and the opportunity for debate. It is still a complex position, however, because of the thought and action which followed my year of stewardship.

There is ultimate compensation in everything, though often transient doubt of it. When I read last June in the inaugural address of the President of the American Medical Association the words, "Organized medicine must keep its relationships adjusted to advancing social conditions and go with the force of public opinion;" and when I read on the title page of the *Iowa State Medical Journal* a few weeks ago these words, "Organized medicine should assume leadership in proposals for the solution of medical problems," I found in these two quotations from my own addresses some of the compensation that I had begun to doubt.

The President of the American Medical Association said in his inaugural address, "Too often we are content with scientific advances and leave the application of them to someone else."

Dean Rappleye said in a recent address that the "science of medicine has not been made available to all people."

Recently the President-Elect of the American Medical Association said that he saw ahead of us the need of a "joint partnership between medicine and the public."

These quotations should be sufficient to show the drift of medical thought and should suggest to organized medicine the need of careful consideration of the situation in medicine between the profession and the public.

More than three hundred personal contacts with groups of medical men in the last three years seem to indicate that the problems of medicine are not in its science but in its relationships; not in its knowledge but in the dis-

tribution of its knowledge; not in its practice but how all people can have its benefits.

The opportunity is here today, (with the work of this House of Delegates limited to one subject), to develop a definite policy toward public health.

The time is about here when we should abandon the defensive and take a cooperative attitude with the public and take part in a straight forward fashion in the solution of medical problems. To fail to recognize the rapidly changing public thought toward prevention of disease is inimical to professional welfare. Yet, there is nothing strange about it after all. The public interest in medicine today is exactly like that which individuals have had since the beginning of history. The only difference is that we have mass opinion instead of individual opinion.

Whether the solution of one of medicine's major problems shall be by the State, supported by public opinion, or under the cooperative leadership of medicine depends upon the decision of organized medicine today.

When the Governor of New York State in the discharge of his duty appointed a year and a half ago a Health Commission of fourteen members with authority to select sub-committees, he created a Health Commission of ninety-two people—fifty-two of them physicians and forty representatives of civic interests or experts in medical research. Among the fifty-two physicians are such men as James Ewing, Burton T. Simpson, Francis Carter Wood, Nathan B. Van Etten, William Snow, William H. Post, Edward R. Baldwin, Lawrason Brown, Edwin P. Kolb, Surgeon-General Cummings, Howard Taylor, William H. Park, W. P. Draper, and Professor E. K. Clarke. The Commission represented the medical and allied professions, every department of the State government having health interests, such as, Mental Hygiene, Industrial Hygiene, Social Welfare, Compensation, and others, and the interests of the general public. The purpose was to study the efficiency of public health practice under the present laws.

The problem of county organization for the administration of public health has been open for the profession to take action since 1922. The thinking public has been looking to the medical profession for leadership in this problem. It has been willing to follow organized medicine.

There are only two basic reasons for a county health department. One is that it offers a sufficient area to provide by general taxation the services that a small area cannot afford to have and, second, the opportunity of a full time staff. The principle of county organization is now recognized in the care of tuberculosis, in public health nursing, in the administration of county laboratories, and in all civic functions of government.

The purpose of a county board of health is to organize such a health department in each county as will meet the health needs of that county efficiently and economically. It is the very essence of home rule because it is done by the county. It has been done by the County Medical Society in Cortland and in Suffolk without dictation from anyone or any agency. It is in local interest because it increases the local availability of preventive measures and control of disease and because of new fields of activity, it increases the work of physicians.

I am puzzled about the criticism of the word, "mandatory." Are the opponents of county boards of health giving the right reason for their opposition? Let us see what use has been made of mandatory.

I have made a personal survey of the three hundred major health laws enacted since 1676. All but three of them have been mandatory. The exceptions are the permissive law of 1850, authorization for consolidation of health districts, and the permissive law of 1922.

Since all laws relating to public health except three are mandatory and no new principle is involved in a reorganization of a local health service, upon what essential is objection based?

It is mandatory that certain requirements be made in order to practice medicine and for every hospital training internes or desiring a rating.

It is now mandatory that cities having fifty thousand population have a full time health officer.

Would you and I register yearly and pay two dollars for it if it were not required?

Certain requirements are mandatory for admission to the American College of Surgeons and the American College of Physicians. It would be an empty honor if it were not so.

The Venereal Disease law of 1931 is mandatory as to health officers providing treatment for indigent cases.

It is mandatory for physicians to report to the Educational Department any handicapped child seen professionally.

The expense of treatment of indigent handicapped children is mandatory on state and county.

Since orthopedic service is in addition a highly specialized service and verges on State medicine, should the law be repealed even though there are forty thousand cases in New York State, some of them not having been seen by physicians and others not adequately treated?

Has medicine ever made a study of public health practice as now done by the one thousand health officers in the state under the present mandatory law or made any effort to ascertain the real facts? As far as I can see the Joint Committee is silent on this point.

If public health is satisfactorily practiced now and if it is in accord with preventive knowledge in medicine, then no change in the law should be made even if it was enacted fifty years ago.

Medicine, itself, has endeavored to have mandatory laws established, for example, the changes in the Compensation Law. Of course, it is not true that medicine has endeavored to have laws in its own interest made mandatory and in the interest of the public permissive. Even though this statement has been made, it should be unhesitatingly controverted.

I would like to escape the word, "mandatory," in my life and I suppose all of you would. I paid some money last month for registering my car because I had to. I paid for licensing my dog because the county said that I had to. We all pay a tax of two cents a gallon on the gasoline we use.

If a mandatory health law is objectionable, then the mandatory law creating township boards of health of 1880 should be repealed and the existing mandatory provision that the compensation of local health officers shall be fifteen cents per capita should be repealed, thus restoring the original power of the town boards of health to fix compensation of health officers.

If "mandatory" is an objectionable word, let us be consistent and get rid of that which we are now working under. The creation of town boards of health was made permissive in 1850 and nothing being done about it, was made mandatory in 1880. County boards of health were made permissive in 1922. Shall they be made mandatory in 1932 or shall the profession say, "Wait for the full thirty years," as once was done—just as if things were moving at only the speed of fifty years ago.

If the mandatory law of 1880 enacted to meet conditions of fifty years ago is good enough to meet the changes and conditions of the present day and present medical knowledge, then I challenge you to say so. It would be better to face the issue in this way than to try to look in both directions at the same time. We should have the courage of our convictions. Is it necessary for organized medicine to placate any element on either side for the question? The profession should say, "We endorse county organization and a full time personnel," and give its reasons as the Committee has done, or it should say, "We oppose it on the ground of its mandatory feature, if that is true, and wish to continue the mandatory law of 1880." Either the 1880 law is still

sufficient or a new one is necessary after fifty years of changing conditions.

The processes of medical history point unmistakably to the future necessity of organization of all publicly and privately supported agencies with medicine for the advancement and availability of all measures for health protection. Should the factual study of the Health Commission and the study of the Joint Committee have reached a common conclusion or is it too much to expect a common ground?

The action of this House of Delegates today on organization for public health administration will be the opinion of the organized profession in this State and not of any one county. It should be remembered that public indifference to the prevention of disease is disappearing with changing times. That this is recognized is shown by the published thought of the leaders of medicine. There has been more attention given to the public relations of medicine in this country in the last five years than in all previous time. We have thought that perhaps New York State had carried "public relations" farther than other states but the more I see of other places, the more I doubt it.

There are more people and more physicians puzzled by the apparent attitude of the organized profession toward its public services than I had any conception of previous to this last six months. I believe that it is in the interest of medicine to clear up the doubt as quickly as possible and I hope that it will be done at this meeting. We need a united profession and organized medicine cannot long endure half progressive and half conservative. There must be somewhere a common ground that every member of the profession can stand for.

I know that I have been discussed a good deal this last year. Certain statements have been made and I, therefore, claim the privilege of personal comment.

During my medical life my only occupation has been the practice of medicine. I have never had a salary paying job and never expect to have. I have never been a health officer and never expect to be.

A few years in the practice of medicine suggested to me that I was a part of the social structure of my community and under obligation to share its responsibilities. I have taken part in the work of lay organizations, chiefly, those of health and civic affairs. I have never found any of them supplanting medicine and I have found in all of them potential sources of supplementing medical service.

I have given fifteen hours a month for seventeen years to the work of tuberculosis care in my county. I hesitate to add the words, altruistic service. I was the head of the physician-guided directorate of the County Tuberculosis and Public Health Association for twelve years.

I have found time to serve as the President for two years of a Chamber of Commerce, representing a territory of four million people, and to take part in its civic work pertaining to health, sanitation, recreation, and community building.

But, the thing of which I am really proud was to offer in my County Medical Society in 1926 a resolution asking for a county organization for the administration of public health and to hear it unanimously adopted; then its establishment by the county and its prominent location among the departments of the county government; its steady increase in appropriations of an average of twenty-eight per cent per year, with unanimous approval. The only comment ever made was, "Have you asked for enough to do a good piece of work?"

At the 1931 annual meeting of the County Medical Society, the largest in its history, an active member who had never been identified with the administration of the department offered a resolution which was unanimously adopted. It said:

"The Suffolk County Medical Society hereby reaffirms its opinion first expressed in 1926 that public health administration can only be efficiently done by county or-

ganization, (to replace township part time organization); that after three years of experience the local profession more strongly than ever believes that the efficiency of public health practice is greatly improved by county organization; and that the physicians of the county have found that a County Health Department is an asset to their professional work and an asset to their economic welfare."

Suffolk County has carried on a County Health Department, initiated by a County Medical Society, longer than any other county in the State. It has met the dictum of the Joint Committee's report which says that a county health unit should be efficient, economical, and progressive; an organization which through the cooperation of the medical profession has benefited the community. The profession has formally registered its opinion that the County Health Department in Suffolk County has been to them a professional and economic asset. All this has come about while increasing the public services of medicine. There has never been any dictation from anybody or any agency in the State. There has been no politics, no bureaucracy, no State medicine, no violation of home rule.

A demonstration has been made in Suffolk County covering a period of five years under the coordinated leadership of the medical profession with all other health agencies. It illustrates what I have been talking about from one end of New York State to the other, that medicine should have a program; that it should adjust its conception of relationship to changing conditions and that by increasing the public services of medicine, the profession's economic structure can be improved and the profession more firmly united under progressive leadership.

I believe, therefore, that it is time for the profession to modify its defensive attitude toward proposals of other agencies to increase the availability of medical service on the sole ground that it will interfere with the physician's income and instead to take a cooperative attitude under the technical leadership of medicine. Let us not sidestep this question. The action of this House of Delegates today on organization for public health administration will be the opinion of the organized profession of this State. It will be the opinion of thirteen thousand physicians. This opinion cannot be concealed within ourselves. It will be the opinion that will go out to twelve million people. It will go out to the people who are puzzled by the apparent attitude of the organized profession toward public health. Our decision may be simply a continuation of the defensive as we have always been on the defensive. Recall the introduction of Laennec's stethoscope, vaccination in Boston, Valentine Mott's use of ether, Oliver Wendell Holmes' Essay on Puerperal Fever.

The public has expected the profession to make use of the permissive law for county organization since 1922. There never has been any objection to the requirement of county boards of health except that stimulated into action by our own profession. I stand on this statement. Public opinion formed as the result of public health education has brought about such a thing in the minds of the thinking public that if we do not undertake to improve public health organization, we open the door by our opposition for the State to do it and then, we advance State medicine by our own act. If we advocate reorganization for the administration of public health we retard State medicine. It is moderately absurd to base objection on the word, mandatory.

I believe that the real objection is the fear of the loss of the positions of the present health officers and fears of what may happen. Many physicians are puzzled as well as laymen by the opposition of medicine to county organization for better public health.

Medicine has not discussed the merits of this question today. I have not heard a single opinion as to whether public health is well practiced in New York State and whether it is in line with public need and

modern knowledge. We need a united profession. We should have wisdom enough to know that our influence depends upon being a united profession. Medicine cannot long endure half progressive and half conservative. Medicine has come to "grips" with itself today in an effort to decide its own policy toward county boards of health.

At a time when, as the result of better health education, medicine and its practice are being better understood and appreciated by laymen, we should be ready to abandon optimistic out-pourings of ourselves that medicine is all right in its relationships and have the courage to face the realities of changing times.

10. VOTE ON SUBSTITUTE MOTION AGAINST MANDATION

Dr. Podvin: If it is in order I would like to move the previous question.

Motion seconded.

The Speaker: Are you all ready for the question?

Dr. Ludlum: Can it be restated?

The Speaker: I am going to ask that the Secretary give us the substance of the substitute motion upon which you are now about to vote.

The Assistant Secretary: Resolved that the Medical Society of the State of New York, realizing that in certain instances the institution of county health units may be desirable, has no objection to this portion of the report with the proviso, however, that such be inaugurated and controlled by local government as already provided under the present Public Health Law (Sec. 4).

The Speaker: You are now voting on the substitute motion of Dr. Rooney.

All those in favor of the substitute motion will signify by saying aye; contrary minded, no.

The Chair is in doubt.

All those in favor of the substitute motion will please rise.

The Assistant Secretary announced 41 in favor of the resolution.

The Speaker: All those opposed will please rise.

The Assistant Secretary announced 54 opposed to it.

The Speaker: The substitute motion is lost.

11. VOTE ON ORIGINAL MOTION TO DEFER MANDATION

The House will now revert to the original resolution of Dr. Goodrich which will be read again.

The Assistant Secretary: Resolved that while recognizing that the principle of county health units is ultimately desirable the House of Delegates record its opinion that the mandatory provision for same be deferred.

The Speaker: All in favor signify by rising.

The Assistant Secretary announced 56 in favor of the resolution.

The Speaker: All those opposed will please rise.

The Assistant Secretary announced 32 opposed.

The Speaker: The motion is carried.

The Speaker: Is there anything further to come before the House?

12. VENEREAL DISEASE

Dr. Aranow: To my conception the rest of the report with the exception of the question of venereal disease is not very important and I want to tell you one thing in my experience last year with this Commission. When the bill was introduced and the question of venereal diseases came out, most men objected; and when we brought the objection to the Commission, the thing was immediately eliminated.

I am quite sure that this Commission now is not in favor of that phase and therefore I think there is absolutely no objection. I think if the Commission would give their report now on that feature, they would suggest that the State take care of the diseases of venereal origin, irrespective of ability to pay. Therefore, I move that the rest of the report be rejected.

Dr. Reuling: I rise to a point of order. I believe that the House voted to take up this report section by section, and the section on venereal diseases comes in later. (See Section 22.)

The Speaker: You are correct.

13. UNITING COUNTY HEALTH DISTRICTS

Dr. Goodrich: In column 2, page 31 of the report in the Journal you will find the substance of the Committee's report involved in this second resolution.

Resolved that when two or more counties desire they shall be permitted to unite in forming a health district and that such health district shall be operated by an organization precisely like the county health unit.

I move its adoption.

Motion seconded and carried.

14. EDUCATING COUNTY SOCIETIES

Dr. Ludlum: We have omitted a recommendation which it is our obligation to consider in accord with our previous resolution. This says: "We recommend that the Medical Society of the State of New York request its Public Health Committee to carry on a campaign of education," and so forth, and we must act on that (Journal, page 31).

I move the adoption of this resolution.

Motion seconded and carried.

15. DEPUTIES TO COUNTY HEALTH COMMISSIONERS

Dr. Goodrich: Resolved that the present local health officer should be retained as a deputy under the County Commissioner of Health.

I move the adoption of this resolution. Motion seconded.

The Speaker: All those in favor signify by saying aye; contrary minded, no.

The chair is in doubt.

All those in favor will please rise.

The Assistant Secretary announced 48 in favor.

The Speaker: Just a moment. I want the negative vote on that resolution.

Dr. Goodrich: The word "President" does not refer to any individual. It refers to the president's office, not the individual.

The Speaker: I will ask for another vote.

All those in favor of the resolution will please rise.

All those opposed will please rise.

The motion seems to be and is carried.

16. NOMINATING COUNTY HEALTH OFFICIALS

Dr. Goodrich: In relation to part of the report near the bottom of column 2, page 31 of the Journal—Resolved that at least three members of the County Board of Health should be physicians and that the present law should be so amended as to give the County Medical Society the opportunity to nominate a panel of physicians from which the Board of Supervisors may make appointments of medical members of the County Board of Health.

Dr. Ross: That is already in the permissive law and has been there under Section 3, Paragraph 17, I believe, about ten years.

Dr. Garen: Is it possible to so change that resolution as to make it read "must" instead of "may"? We have heard a good deal of criticism of permissive things today, and praise of compulsory or mandatory things.

Well, let us make it mandatory, if mandatory is such a good thing. Let us make it mandatory that supervisors appoint three physicians instead of simply giving us the wishy-washy permissive thing that they may appoint three physicians on that county board.

The Speaker: Dr. Garen, do you offer an amendment that substitutes the word "must" for the word "may"?

Dr. Garen: Yes sir.

The Speaker: Is that motion seconded?

Dr. Farmer: I would like to speak for the Committee on that.

The Committee would like very much to have it just as Dr. Garen has explained, but legally that is impossible. You can't compel an appointing officer to make appointments. It is impossible legally.

Dr. Goodrich: I was simply going to say that point has been ruled upon as unconstitutional by the Counsel of the State Society.

The Speaker: Dr. Garen your motion is illegal will you withdraw it?

Dr. Garen: I withdraw it.

The Speaker: Are you ready for the previous question?

All in favor signify by saying aye; contrary minded, no. So ordered.

17. COMMUNITIES OF 50,000 POPULATION

Dr. Goodrich: Resolved that only incorporated communities of 50,000 or more of population shall have the option of exclusion from the county health unit.

Dr. Leinert: What is meant by a community? A whole county or city?

The Speaker: I will ask Dr. Goodrich to answer your question.

Dr. Goodrich: I would like to pass it on to the Committee. This is simply a boiling down of the Committee's report.

The Speaker: I will ask Dr. Farmer if he will answer Dr. Leinert's question.

Dr. Farmer: The Committee felt that if a county health department was worthwhile at all it was worthwhile for every citizen, and that in a county say, of 75,000 population that an incorporated community of 35,000 might exclude itself and not have the benefit of full time administration of health personnel while the other 40,000 did. The law as passed now makes it obligatory that every incorporated community of 50,000, every city of 50,000, shall have a full time health officer, and it was to bring this in line with that that we felt that communities under 50,000 and perhaps over 5,000 would be operating under the old way of doing things, which is not as progressive as the newer way under the county health department. Therefore, it should be "incorporated community." That word should be in.

The Speaker: The proponent of the resolution accepts the word "incorporated."

The Speaker: All in favor signify by saying aye; contrary minded, no. So ordered.

18. MONTHLY MEETINGS OF COUNTY BOARDS OF HEALTH

Dr. Goodrich: Resolved that Legislative provision for the specified monthly meetings of the county boards of health shall be made by proper amendment.

The Speaker: All in favor signify by saying aye; contrary minded, no. So ordered.

Motion carried.

19. ADVISORY COMMITTEE OF PHYSICIANS

Dr. Goodrich: Resolved, that an amendment shall be offered providing for an advisory committee to each county health board composed of three to five physicians appointed by the County Medical Society. Said advisory committee shall have the right of attendance with voice but without vote at all meetings of the board.

I move the adoption of the resolution.

Motion seconded.

The Speaker: All in favor signify by saying aye; contrary minded, no. So ordered.

20. DISSOLUTION OF COUNTY BOARDS OF HEALTH

Dr. Goodrich: Resolved that that part of the present law providing for the dissolution of the County Boards of Health be retained.

I move the adoption of the resolution.

Motion seconded.

The Speaker: All in favor signify by saying aye; contrary minded, no. So ordered.

Motion was carried.

21. CITY HEALTH ADMINISTRATION

Dr. Goodrich: I move that we approve of the principle that full-time health officers be provided for cities of fifty thousand or more population.

Motion seconded.

The Speaker: All in favor signify by saying aye; contrary minded, no. So ordered.

Motion was carried.

* 22. VENEREAL DISEASES

Dr. Goodrich: I move the approval of the section on Venereal Diseases. (See the Journal, page 24. See also Sec. 12.)

Motion seconded.

The Speaker: Is there any discussion?

Dr. Rosenthal: I believe it should be made mandatory, that in all the smaller towns venereal diseases should be treated by private physicians and paid for out of public funds.

Dr. Bonnar: I do not think the public should be taxed for the treatment of self-imposed diseases, especially for those who are able to pay. If they are able to pay they should pay directly to the attending physician. If they are indigent people I think then that motion might prevail. Otherwise, personally I cannot agree to it. Every man that is able to pay should pay directly. Those who are indigent and not able to pay might be considered.

The Speaker: You are voting on the adoption of that portion of the report relative to Venereal Diseases.

All in favor signify by saying aye; contrary minded, no. So ordered.

Motion was carried.

23. CANCER

Dr. Goodrich: I move you this body record itself in favor of the recommendation "That educational work either public or professional on the subject of cancer should be done in close cooperation with the Medical Society of the State of New York and the American Society for the Control of Cancer (Journal, page 32)."

Motion seconded.

The Speaker: All in favor signify by saying aye; contrary minded, no. So ordered.

Motion was carried.

24. MATERNITY CARE

Dr. Kosmak: In reference to the section on maternity (Journal, page 32), I offer the following resolution:

Whereas recent and careful studies have shown that improved maternity care is dependent upon a coordination of existing agencies which shall include every stage of this process, and that improvement in the education of physicians, nurses and midwives is the most important factor in providing safe and satisfactory obstetric care, therefore be it

Resolved, that this recognition and the requirements for bringing about a change is of greater consequence and importance than the further organization of county-wide health services for this purpose, and furthermore be it

Resolved, that the function of a health department should be of a supervisory character, by establishing standards for proper obstetric practice and by studies of State-wide conditions, the results of which may be applied to the solution of local problems, rather than by direct provisions for pregnancy care.

I move the adoption of these resolutions. Motion seconded.

The Speaker: All in favor will signify by saying aye; contrary minded, no. So ordered.

Motion was carried.

25. SCHOOL HYGIENE

Dr. Kopetzky: I move the adoption of the section on School Hygiene as printed (Journal, page 33).

Motion seconded.

The Speaker: All in favor signify by saying aye; contrary minded, no. So ordered.

Motion was carried.

26. ORTHOPEDICS

Dr. Goodrich: I move the adoption of the section under the heading of Orthopedics as printed (Journal, page 33).

Motion seconded.

The Speaker: All in favor signify by saying aye; contrary minded, no. So ordered.

Motion carried.

27. PUBLIC HEALTH NURSING

Dr. Goodrich: I move the adoption of the section under the heading of Public Health Nursing (Journal, page 33).

The Speaker: There is no recommendation there. Do you want a motion on it?

28. INDUSTRIAL HYGIENE

Dr. Goodrich: I move the adoption of the section on Industrial Hygiene.

Motion seconded.

The Speaker: All in favor of adopting that portion of the report which deals with Industrial Hygiene manifest it by saying aye; contrary minded, no. So ordered.

Motion carried.

29. PUBLIC HEALTH PERSONNEL, AND HEARINGS ON THE STATE SANITARY CODE

Dr. Kopetzky: I move the adoption of the following section on Public Health Personnel.

"Realizing the importance of authoritative medical representation on the Public Health Council, your Joint Committee recommends the consideration of a plan whereby the State Medical Society shall have the privilege of submitting to the Governor of the State of New York a list of suitable names from which he may make appointments when filling the place of a medical member of the Public Health Council."

Motion seconded.

Dr. Farmer: I would ask Dr. Kopetzky if he would include in that recommendation the recommendation in the paragraph before which the Committee feels is very important, recommending "That provision be made in the Public Health Law to require the Public Health Council to hold open hearing upon proposed regulations for changes in the Sanitary Code before their adoption."

Dr. Rooney: I ask Dr. Farmer if there is embodied in this, the resolution which he proposed at the last meeting of the House of Delegates and which was referred to this one, that no mandatory regulations made by the Public Health Council, be effective for a period of at least six months after their promulgation.

Dr. Farmer: It is not, and I think it would be acceptable.

Dr. Rooney: I move as an amendment that there be embodied in this resolution by Dr. Kopetzky that the Society further recommends that where promulgations of regulations are made by the Public Health Council that they be not effective until a period of at least six months has elapsed followed their promulgation and after hearings have been permitted to the medical profession of the State in relation to those amendments.

Dr. Kopetzky: I will accept the amendment, adding the word "open."

Dr. Groat: I have no vote in this, but I am not sure but what there might arise occasions where we would want a regulation put in effect sooner than six months, even though it were made by the Public Health Council. It seems to me it might be left to their discretion.

Dr. Rooney: I think that the House might well be informed that under the present law regulations of the Public Health Council when promulgated have the force of statutory law. They are given legislative power by the act which made them. I can see, I confess, no necessity for any emergency likely to arise that would require an immediate mandatory provision by the Public Health Council in the way of certain regulations. The Public Health Law today covers their complete control in relation to epidemics.

My own feeling is this, that the difficulty has been largely by the medical profession in this State with the Public Health Council, these star chamber sessions, and the promulgation of resolutions and regulations which become statutory immediately upon promulgation without any opportunity for hearing upon the part of the medical profession and with no medical cooperation and coordination.

I feel that the objection raised by Dr. Groat is not valid and I trust that the House will so hold. The law gives the Public Health Council or gives the Commissioner of Public Health absolute and complete police powers after the term of any epidemic, irrespective of the Public Health Council which is purely advisable. The Commissioner of Public Health can do absolutely anything he chooses at times of emergency. This will not prevent his power but will prevent the Council from enacting star chamber legislation. I hold to my original position.

Dr. Farmer: I agree absolutely with Dr. Rooney. It is entirely correct.

Dr. Groat: I was thinking of some emergency which might arise which, Dr. Rooney has stated the Commissioner of Health has the power to handle. That was the point I wanted to make, I understand it now.

The Speaker: All in favor of the resolution signify by saying aye.

Dr. Rooney: As amended.

The Speaker: As amended, yes. All those opposed, no. So ordered.

30. ADOPTION OF REPORT AS A WHOLE

Dr. Kopetzky: We have adopted the report of the Joint Committee in sections, and now I move you, sir, the adoption of the report as a whole as amended this afternoon.

Motion was seconded. (See Sec. 32.)

31. PRINCIPLE OF STATE AID

Dr. Johnson: I want to draw your attention to the fact that you have overlooked one section, one of the most important. Dr. Farmer very justly and very truly said that the meetings of this Committee were harmonious. I was allowed to sit in and talk, but I was the old woman of the Committee. A woman convinced against her will is of the same opinion still. I went there with a couple of convictions. Somebody said, "Opinions fill no cathedrals. Cathedrals are built by convictions." And that was on the question of principle. That is the question of State aid. That was the one I differed with the Committee on and they allowed me to differ, very kindly. I think that the principle of State aid is one that is worthy of some discussion, and it has not been taken up.

I feel that State aid becomes State subvention and finally a bribe. In the hands of those who have the handing out of State aid. And I would like to hear a few expressions of opinion before we adopt this report as a whole; what the men think about the principle of State aid.

You notice our Committee handled it with gloves. We slid around it. I would like to hear that discussed.

Dr. Kopetzky: I move, sir, that the motion to adopt the report as a whole as amended be tabled so that we can take up the question raised by the President.

Motion seconded.

The Speaker: The motion has been made and seconded.

that the motion for the adoption of the report as a whole as amended be tabled. All in favor signify by saying aye, contrary minded, no. So ordered.

The motion was carried.

The Speaker Is there anything further to come before the House of Delegates?

Dr Rooney The President has raised this question as to what position the Society is to take on State aid.

I do not know that I am in order in discussing it except upon the motion made by Dr Kopetzky as to the adoption of the report as a whole. That having been tabled I fear that unless some motion is made I probably am out of order. So that for the purpose of eliciting discussion I will move, that the House of Delegates of the Medical Society of the State of New York is in favor of State aid.

The motion was seconded.

Dr Heyd In order to command a vote on this without discussion I move that the House of Delegates go into a Committee of the Whole informally with the Chairman occupying the chair. In doing that we can discuss our opinions without moving for a vote on the question until we have consolidated our ideas.

Motion seconded.

The Speaker It has been moved and seconded that the House of Delegates go into a Committee of the Whole for the discussion of this State aid proposition. All in favor signify by saying aye, contrary minded, no. So ordered.

The motion was carried.

The Committee of the Whole of the House of Delegates of the Medical Society of the State of New York was called to order by Dr John A. Card, Speaker of the House of Delegates.

Dr Goodrich As long as the Joint Committee has given us a report saying it feels that it has not the necessary information to make a definite pronouncement on the general subject of State Aid which it believes is a subject of great importance and merits study by medical, economic and legislative authorities I move that it is the opinion of this Committee to be reported to the House of Delegates that action on the question of State aid should be postponed until the regular meeting of the House of Delegates this coming year and that the Joint Committee be asked to bring us further data at that time.

Motion was seconded.

Dr Card You have heard the motion. Is there any further discussion? All in favor signify by saying aye, contrary minded, no. So ordered.

Motion was carried.

Dr Goodrich I move that the meeting of the Committee of the Whole be closed and that we report to the House of Delegates.

Dr Dougherty I move that the Committee rise and that the secretary report its action to the House.

Motion seconded and carried.

The Chairman The meeting of the Committee of the Whole is adjourned.

Following the recess which had been taken to permit

of a meeting of the Committee of the Whole, the Special Session of the House of Delegates was resumed and called to order by the Speaker.

The Speaker The House of Delegates will now come to order and we will listen to the report of the Committee of the Whole.

Dr Goodrich I will ask the Secretary to make the report.

The Assistant Secretary Resolved that action on State aid be postponed until the next meeting of the House of Delegates and that the Joint Committee be asked to bring further information at that time.

Dr Kopetzky I move the adoption of the report of the Committee of the Whole.

Motion seconded.

The Speaker All in favor signify by saying aye, contrary minded, no.

Motion was carried.

32 ADOPTION OF REPORT AS A WHOLE

Dr Kopetzky I move to take from the table the motion to adopt the report of the Joint Committee (Sec 30).

Motion seconded.

The Speaker All in favor of the motion signify by saying aye, contrary minded, no.

Motion to take from the table was carried.

The Speaker The motion before you now is the adoption of the report of the Joint Committee on the Governor's Health Commissions Report as a whole as amended by the House of Delegates today.

The Speaker All in favor signify by saying aye, contrary minded, no. It is so ordered.

Motion was carried.

33 THANKS TO JOINT COMMITTEE

Dr Kopetzky As one of those who helped to make the decision of the House today I want to make a motion thanking the Joint Committee for their arduous labors in behalf of the profession.

Dr Rooney I rise with great pleasure to second the motion of Dr Kopetzky.

I think the Committee deserves the thanks of the House.

The Speaker You have heard the motion. All in favor signify by saying aye, contrary minded, no. It is so ordered.

Motion was carried.

34 ADJOURNMENT

The Secretary I move that we now adjourn.

The Speaker You have heard the motion. All in favor please rise.

Motion carried and the House adjourned at 4:45 P. M.

Respectfully submitted

JOHN A. CARD, Speaker

DANIEL S. DOUGHERTY, Secretary

Dr. H. Goodrich

NEWS NOTES

MEDICAL ECONOMICS CONCERNING INDUSTRIAL MEDICINE

From the Committee on Economics of the Medical Society of the State of New York.

Industrial medicine or medicine in industry is no different than medicine in any other part of our social scheme. We have occasionally defined it as good medicine as applied to industry. The attitude of organized medicine toward this particular phase of medical occupation should, I believe, be one of cooperation, and at the same time one of standardization. There is no doubt but that medicine in industry has come to stay, and that in a large part, industry was forced into its present position by way of the compensation laws, plus the reaction of the profession in general toward the arbitrary rulings in what have been deemed professional matters.

In the State of New York, there is plenty of legislation which covers the subject of the practice of medicine. This legislation takes the very definite stand that corporations cannot practice medicine. There are a few industrial organizations in this state which conduct very extensive and very comprehensive medical services both in sickness and in accident for the benefit of their employees. These several services, as viewed from the standpoint of the average practicing physician, take on the appearance of corporation medicine. Nevertheless, if the subject is scrutinized with care, it will be seen that in all cases the responsibility rests with the doctor who renders the service; and even though he may accept a salary from the corporation within whose confines he is carrying on his medical activities, nevertheless, his dealings are with the patient; and inasmuch as the patient in no wise is allowed to compensate him, the legal opinion is that such endeavors do not constitute the corporation practice of medicine.

We do, however, see a very widespread attempt to avoid this very issue in the employment of a medical supervision exercised in a questionable capacity over the activities of the first-aid worker and the trained nurse. The difficulty in differentiating between medical service to employees of the type which would be concurred in by the medical profession at large, centers about the term "first aid." Where there is strict adherence to the letter of the understanding the application of the meaning "first aid" is a perfectly satisfactory solution. However, the day to day rendering of so-called first-aid medical and surgical treatment constitutes little less than the providing of medical service to the employee of a type which might be rendered by the patient's family physician. I believe that many industries, and more or less

unconsciously, their medical people, are offenders against the meaning of this term. The employee, great or small, who is able to go to the job and yet is hampered more or less by reason of a physical or mental disability, should have recourse to easily obtained adequate and inexpensive medical and surgical care. This the medical profession in most communities is unable to supply; and even if they were, such employees would not resort to them for relief inasmuch as in the majority of instances they would consider their discomforts of a not sufficient degree of magnitude to warrant spending money with their doctor. Furthermore, recourse to company facilities under such conditions, while costing nothing, conserves time and enables them to return to work with a more comfortable ability to perform. Or they are sent home with diagnoses of varying degrees of correctness, to seek the ministrations of their local physicians. Viewed in the light of other industrial expenditures of the nature of operating costs, the fixed charges for such endeavor do not form an item of great importance; and with the application of business methods, organizations are able to provide this kind of service in a degree not possible by the average practicing physician even though he may be advantageously located. The matter of compensation varies and, by and large, we do not consider it adequate viewed in the light of the earning capacities of physicians at large. It is the experience of those of us who have been in the executive medical field over a period of time that the number of medical persons seeking this sort of work as a permanent occupation has been constantly increasing. We will always have the young doctor who is in need of temporary quick financial return and it is quite proper that occupation of this kind be made available for him. At the same time it should be within the realm of organization control that the precepts of the profession be maintained and that medical ideals should not be allowed to lapse during the period of their industrial endeavor. Fortunately, we are past the time when the plant physician and surgeon is viewed by his fellow members of the profession as a medical or surgical incompetent classified under the term "company doctor." By and large, within industry today where executive cooperation has blended with professional skill and ambition, the quality of medical and surgical service while of a first-aid character is a direct contribution not only to the employees but to the family physician as well. A properly conducted

medical department is a feeder for the local physician even though for economic reasons diagnostic investigation of first aid problems are not possible. Likewise there is a direct result to the patient himself which is of more moment than any personal economic accrual to himself is con-

cerned. Organized medicine should recognize that it has a part to play in the maintenance of those qualities which should make for professional dignity as embodied in conduct, economic returns and character of the professional product delivered.

CASSIUS H. WATSON

COMMITTEE ON LEGISLATION

Bulletin No. 1

January 26, 1932

We are happy to state that reports from the field indicate that the county committees are going to be unusually active this year. More chairmen have reported to us upon their organizations and their plans for work than in any previous year at such an early date. Naturally, we are encouraged and we shall do our utmost to make ourselves and the Bureau in Albany as useful as possible. We hope that every chairman will feel free to call upon us for assistance and information at any time. We can expect a busy year. While there are rumors that the legislature is likely to have a short session, there is no doubt but that there will be the usual run of bills in which we shall have a deep interest. The anti-vice bill, an annual visitor, has made a very early appearance this year. Bills now before the legislature are:

Senate Int. No. 11—Dr. Love has reintroduced his "baby mixing" bill. Referred to Codes Committee.

Senate Int. No. 71—Hastings, creating a division of medicinal liquor to which is delegated powers to carry out provisions of proposed law relating to prescriptions, sale and use of intoxicating liquors for medicinal purposes and appropriating \$250,000. Referred to Finance Committee.

Senate Int. No. 79—Mastick, an amendment to the Workmen's Compensation Law by providing compensation for all diseases arising out of employment. Referred to Labor Committee. This bill has been before us on two preceding years.

Senate Int. No. 256—Westall, would amend the Public Health Law by providing each city becoming part of a county health district shall be entitled to one additional representative on county health board all members of the board to be residents of the health district. Referred to Health Committee.

Senate Int. No. 324—Berg, would amend the Education Law by extending to six months after May 17, 1932, time for applying for a license to practice physiotherapy under the act. Referred

to Education Committee. The time for physiotherapists to apply for a license expired by law May 17, 1926. Senator Berg by this bill would open the matter again and permit applications to be made for this period of six months in this year. We know of no reason why another opportunity should be given physiotherapists for registration. The bill has just come to our desk and we have not had an opportunity to inquire of Senator Berg or of the Department of Education as to the necessity for such bill. We shall make further report in our next bulletin.

Senate Int. No. 328—Berg, would amend the Education Law to permit restoration by Regents of a license for the practice of medicine to a person pardoned after conviction of felony, for misconduct in his professional capacity. Referred to the Education Committee. Senator Berg's amendment is to delete from the law the following: "Unless such conviction has been for misconduct in his professional capacity."

Senate Int. No. 331—Gates, would amend the Education Law to permit an optometrist or physician to prescribe for and furnish spectacles, eye glasses or lenses to a person "upon request." Referred to Education Committee.

Assembly Int. No. 116—Doyle, is a modified form of the bill which Mr. Doyle had last year regulating the sale and manufacture of bichloride of mercury and compounds thereof, to prevent accidental poisoning. Referred to the Codes Committee. The bill in its present form was considered by this committee and approved. If you find that there is reason why this is unwise legislation we hope you will give us your opinion at an early date.

Assembly Int. No. 261—Vaughan, the anti-vice bill.

* * *

The osteopaths have had some conferences with the Department of Education regarding what they have been seeking in past years, and Dr. Johnson our president, has been invited by the Department of Education to attend a conference and bring with him such members of our Society as he may name. The conference will be held on Thursday

in New York City. This committee has been invited and it is our understanding that representatives of the osteopathic society will also be present.

The anti-vivisection bill has been introduced in the Assembly only and rests with the Codes Committee, whose personnel follows:

Burton D. Esmond, Chm..Saratoga Co.
James R. Robinson.....Tompkins Co.
Willis H. Sargent.....Onondaga Co.
Edward M. Sheldon.....Lewis Co.
Walter W. Abbott.....Oneida Co.
William J. Lamont.....Orange Co.
Howard W. Dickey.....Erie Co.
Daniel J. O'Mara.....Monroe Co.
Oswald D. Heck.....Schenectady Co.
Meyer Alterman.....New York Co.
Wm. C. McCreery.....Kings Co.
Harry A. Samberg.....Bronx Co.
Saul S. Streit.....New York Co.

Won't each of you whose Assemblyman is a member of this committee immediately get in touch with him and establish your opposition to the advancement of the bill? The Anti-Vivisection

Society does not expect to have the bill enacted into law, but they demand that the committee shall report upon it favorably so that it may be debated on the floor of the Assembly.

* * *

HEARINGS

While writing this bulletin, information has come from the Codes Committee that there will be a hearing on the anti-vivisection bill on Tuesday, February 9th, at 2:00 P.M. The members of the committee report that they are being flooded with letters from persons not only in New York State, but from all over the world, urging favorable consideration of this bill. It is, therefore, important that every chairman take the matter seriously and see that letters in opposition to the bill are sent to the members of the committee and especially should there be letters from prominent men and women who are not physicians.

HARRY ARANOW,
JOHN J. BUETTNER,
MARSHALL CLINTON,
Committee on Legislation.

Letter to County Committees

The following letter has been sent to the Chairmen of the Legislative Committees of County Societies under the date of January, 30, 1932:

Enclosed you will find the following bills and we hope you will read carefully what is written in italics, which is the new part. In some bills, however, where there is an entirely new section added, the new part is not written in italics. Let us have your comments whether you are for or against the matter, and your replies particularly if you are in opposition. You may say that we know what your reaction would be, but, nevertheless, you would be surprised to know how many times we get valuable suggestions from men who state to us the very things we had in our mind:

Senate Int. No. 256-Westall, to amend the public health law in relation to the members constituting the county board of health. In Westchester County, from which Senator Westall comes, there is a county health unit operating and about a year ago the City of White Plains decided to come into the unit, and it understood that the health officer of the city would be made a member of the county board of health and, accordingly, the county health department appointed a deputy to the commissioner, to be in charge of health activities in White Plains. When the time came for election to the county board of health, the supervisors chose to return the physician who was a member of the board,

and not to replace him with the retired health officer of White Plains. This bill is to meet a situation of that kind and seems to us to be a fair proposition. We expect to ask Senator Westall to amend this bill in line 7 on page 2, changing the word "two" to "three." This will be in accordance with action taken by the House of Delegates at the recent special meeting and also in accordance with the recommendations of the Governor's Special Health Commission.

Senate Int. No. 324-Berg, to amend the education law, in relation to licenses to practice physiotherapy. Mr. Berg says that there are six or eight physiotherapists who, although entitled to do so, failed to make application for license in 1926, and he would like to give them an opportunity. We do not think it wise to reopen the matter which was closed six years ago. We believe that all the persons who were entitled to licensure at that time had ample opportunity to make application for such license if they desired it. We believe that the Department of Education supports us in this opinion.

Senate Int. No. 328-Berg, to amend the education law in relation to restoration of licenses for the practice of medicine to persons pardoned after conviction for a felony. This needs no explanation; you can understand it as well as we. Give us your opinion.

Senate Int. No. 331-Gates, to amend the education law in relation to peddling of spectacles, eyeglasses or lenses by optometrists or physicians. You will note that the

amendment here is very small, it simply introduces the phrase "upon request" permitting a physician or optometrist to prescribe and furnish spectacles to any person upon request. Give us your opinion as to the value of this amendment.

Assembly Int No 261, is Mr Vaughan's annual "dog bill," identical with the bill of last year.

In order that our records may be correct and complete will you please let us know if

you are not the chairman of the County Society Legislative Committee or the proper person to receive bills in your county. We regret that we cannot regularly send all of the bills to every person who makes requisition, but we do want to send them to the chairman of the County Society committee and we frequently can send several bills to others, upon their requisition.

HARRY ARANOW, *Chairman*

PRIZE ESSAYS

The Committee on Prize Essays desires to call the attention of the medical profession to the following prizes offered through the Medical Society of the State of New York.

The Merritt H. Cash Prize. This prize was established by Dr. Merritt H. Cash in 1863 and is given to the author of the best original essay on a subject designated by the Committee on Prize Essays. Competition is limited to the members of the Medical Society of the State of New York, who at the time of entering the competition are residents of New York State.

The essay shall be typewritten or printed and the only means of identification of the author shall be a motto or other device. It shall be accompanied by a sealed envelope having on the outside the same motto or device and containing the name and address of the writer.

An idea of the type of subject upon which competitors may write their essays is indicated by the list of previous awards of this prize which is as follows:

- 1864—A. N. Bell, Brooklyn "How Complete Is the Protection of Vaccination, and What Are the Dangers of Communicating Other Diseases with the Vaccina?"
- 1913—William Kirk, Jr., Troy "Brown Sequard Paralysis: Review of Subject with Summation of Cases and Report of Case Resulting from Stab Wound of Autopsy."
- 1920—Hernan B. Sheffield, New York City "Present Status of Poliomyelitis."
- 1923—Arthur M. Wright and Edward M. Livingston, New York City "Eucocytosis of Internal Hemorrhage."

The Lucien Howe Prize. In 1906, the late Dr. Lucien Howe, then residing in Buffalo, presented the State Medical Society with a prize fund, the interest of which is to be used by the Society for the presentation of a suitable medal for the best original contribution to our knowledge of some branch of surgery, preferably ophthalmology. The author need not be a member

of the Medical Society of the State of New York.

The method of presenting the communication and of awarding the prize shall be substantially the same as that followed in regard to prize essays. That is to say, the communication shall be typewritten or printed, and the only means of identification of the author shall be a motto or other device. It shall be accompanied by a sealed envelope having on the outside the same motto or device, and containing the name and address of the writer. If, in any year, the committee does not deem any essay or communication which is offered worthy of the prize, then it shall not be awarded, and the interest for that year shall be added to the principal.

In the past this prize has been awarded as follows:

- 1914—Mark J. Schoenberg, New York "Contribution to the Experimental Study of Ocular Anaphylaxis."
- 1918—Israel S. Wechsler, New York City "Ophthalmic Changes in Tabes and Paresis—Pathology and Diagnosis with Reference to Cerebrospinal Syphilis."
- 1922—Arthur J. Bedell, Albany "Some Observations with the Gullstrand Slit Lamp on the Lens Including Cataract."
- 1924—Arthur J. Bedell, Albany "Study of the Vitreous."
- 1927—Arthur J. Bedell, Albany "Photographs of the Fundus Oculi, Normal and Pathological Conditions."

Prize essays must be submitted before May 9th. They must be directed to the Committee on Prize Essays, Medical Society of the State of New York, 2 East 103rd St., New York City.

If any identification marks other than the ones prescribed are attached to the essay, it will be debarred from the competitions.

E. MACD. STANTON, *Chairman*,
ALBERT C. SNELL

Committee on Prize Essays

PUBLIC RELATIONS COUNTY SURVEY NUMBER 20—WESTCHESTER

The Public Relations Committee of the Westchester County Medical Society desires to make the following report:

Following its appointment at the commencement of the year, the committee organized and considered various outlets for its activities. After due consideration we decided that there were a number of conditions existing in the practice of medicine in this county which might be improved, and we felt that if we could develop in some one community some steps tending to improve these conditions, the remaining communities would follow suit. Among the conditions in which we felt there was opportunity for our work were:

(1) In the majority of communities there is no way by which any individual desiring a physician in an emergency and being unable to secure his family physician can secure the services of a doctor without indiscriminate telephoning to all the doctors in his community. Even if the latter procedure is adopted, it is often impossible to secure help. The committee felt that it was desirable to make some arrangement with the hospital in each community whereby this institution would agree to utilize its forces in securing some physician practicing in the neighborhood of the patient for such an emergency. With this arrangement established, the public should be advised of the fact. In every way possible everyone should be informed, "In case of any emergency where you are unable to secure the services of your family physician, telephone the hospital." As a result of our work, in the annual hospital statement 15,000 residents of New Rochelle and its vicinity have been advised of the above-named procedure, and through the medium of the press the general public is to be later informed. It is too early as yet to give any definite results of this plan, but we believe it will be of service.

(2) We know that in the majority of hospitals in the county no social service worker is employed. We feel that our dispensaries are being used by many patients who are able to pay for the services of a doctor, and we feel that a more careful investigation of the financial condition of these patients is advisable. The chairman of the committee appeared before the Board of Governors of the New Rochelle Hospital, stated the situation and asked for the employment of such a worker. This request was granted and the proper person was employed. Unfortunately, after working for a short time, this party was taken ill, was incapacitated for a number of weeks, and finally obliged to resign. A second party, however, was employed a few weeks ago and is now developing our ideals. As a result of her investigation, the dispensary patients appear to be classified into three divisions: (a) those who are

unable to pay anything more than the small minimum charge of 25c or less; (b) those who are able to pay more than 25c but not able to pay the usual fee for a visit to a doctor's office; (c) those who are able to pay the usual fee of a physician. We have found many cases who belong to Group C, and these patients are unhesitatingly refused treatment in the clinic after their immediate wants have been attended to. We have found that Group B included many cases and a plan is being developed whereby these patients can pay a fee that is in proportion to their means, the proceeds going to the attending physician.

This social service worker is now busy in many directions; she is investigating the financial condition of many dispensary cases; she is doing the same for some ward cases; she is following up ward cases after they have been discharged from the hospital, and she is doing the same work for dispensary cases where necessary. We feel that her work will be invaluable to the community, to the hospital and the doctors; we feel that the money she will collect for the institution will more than pay her expenses; we feel that in all probability additional help will have to be given her as this work progresses. We hope that the activities of this department of the hospital can be extended so that it can be employed by the staff of the institution to investigate and report to the doctors on cases desiring special treatment but who claim to be unable to pay the usual fee.

We have addressed a meeting of the hospital superintendents of the county, explaining to them the ideals of this committee, telling them of the plan that we hope to develop in the New Rochelle Hospital, asking them to observe its results, and, if they find these results desirable, requesting them to follow suit. At present we definitely know, by requests of neighboring hospitals, that they also realize the needs of this work and are watching our progress.

The committee realizes that its work has extended only over a period of a few months, but it feels that it has made an earnest effort along the lines indicated and sincerely hopes that the work it has started will be continued by the coming committee. We feel that it represents a very important condition existing in the practice of medicine at present. We believe that the hospital should be the medical center for each community, but we do not believe that the hospital should practice medicine. The doctor is entitled to his fee, the public should receive medical service, but just as the medical profession should not be imposed upon by those able to pay for medical care, neither should the cost of this medical care be a financial tragedy to the patient.

C. C. GUION, *Chairman.*

PUBLIC RELATIONS COUNTY SURVEY NUMBER 21—YATES

The Committee on Public Relations of Yates County Medical Society, having made a survey of the welfare and public health activities in the County, wishes to report to the society at this time.

Yates County, which has been known as Little Yates for some time, is located in the midst of the Finger Lakes Region, and is one of the smaller counties in the state, being only about eighteen miles long and thirteen miles wide. The population is 16,848, of which 5,329 live in the county seat of Penn Yan. There are only nine townships in the county and four incorporated villages, namely, Rushville, Dundee, Dresden and Penn Yan.

One of the oldest public welfare organizations is the Tuberculosis and Public Health Committee, which was organized on the 24th of May, 1921, with Dr. A. T. Halstead of Rushville as first president. This committee derives its entire support from the county's share in the sale of Christmas seals and consists of one supervisor from each township and the officers. Most of their work is carried on through the county nurses, but they do some relief work aside from this. The present medical member of this committee is Dr. J. P. MacDowell of Dundee.

We are not able to learn just when the Yates County Committee of the American Red Cross was organized but it has 23 members and is self-perpetuating. Last year, it spent \$300 through the public health nurses of the county, \$200 for food for needy families, and \$100 for courses in life saving for boys and girls. This year it has appropriated \$300 for eye, and adenoid and tonsil work.

The local Committee for Cancer Control has been organized for several years. Its chairman is always the chairman of the cancer committee of this society. There has been little activity for the last two years because of the re-organization of the state committee. But there is at the present time a movement on for a public meeting to be held in the near future, at which we hope to have the president and executive secretary of the State Society, who have promised to show several reels of moving pictures, issued by the state committee for public instruction.

For a few years there was a milk commission in Yates County of which the chairman and two members were elected from this society; but as the production of certified milk has been discontinued, the commission is now inactive.

During the past year, the Parent-Teachers Association has been addressed by several local doctors on different health problems.

Yates County has two full-time public health nurses, who reported the following activities in 1931:

Medical cases visited	45
Infants	395
Tuberculous positive	70
Tuberculous suspects	60
Pre-school examinations	1,107
Chest clinics, state doctor	4
Orthopaedic clinics, state doctor	2
Rural consultations—local physicians.	15
Regular consultations	37
Vaccination clinics	6
Toxin anti-toxin clinics	3

The Yates County Laboratory was established in 1925 under a committee of the County Supervisors with three medical members. The laboratory is located in the Yates County Soldiers and Sailors Memorial Hospital, and during the past year it has handled about 5,000 specimens, about one-third of which have been public health cases and two-thirds hospital cases. The biopsy specimens are sent to the State Cancer Laboratory, and the serological ones to Albany. There have been between 300 and 400 specimens of milk, and 100 of water examined during the year. The Laboratory is under the supervision of the Director of the Ontario County Laboratories with a technician, recommended by the State Health Department, in charge.

There were only three toxin anti-toxin clinics held during the year 1931 because as far as we can learn, there was little need of them in most of the townships. One township reported that all but two families had been taken care of up to January 1, 1931, and one township reported 80 children to be immunized this year, there having been no clinics for lack of funds during 1931. The county nurses estimate that more than 80 per cent of all children between six months and ten years in the county have been immunized.

In 1922, the Cripple Children's Committee of the local Rotary Club was organized, and joined the State Association of such committees. They made a survey of the county and found 150 crippled children and grownups, some of which were classified later as adenoid and tonsil cases. Many of the throat cases were operated on with the assistance of the committee. Its work has been less each year until 1931, when it was looking after five cases of post-polio conditions. Each week they have been taken to Geneva where they have the advantage of the Y.M.C.A. swimming pool, and have been under the supervision of state orthopaedic nurses.

The County Medical Society has sponsored the rural pre-school examination since 1925, working in conjunction with the county nurses and children's agent, together with the District Health Officer. Formerly, there were at least two clin-

ics held in each township each year, but because of lack of funds, only one is now held. Some of the townships having more children than can be handled at one clinic, are assigned two clinics on the same day, which accounts for the fifteen held last year as given in the nurses' report.

Yates County has one hospital with 38 beds, which is located in Penn Yan, the county seat. While it is known as Yates County Soldiers and Sailors Memorial Hospital, it was built by public subscriptions and is self-supporting, except for a few legacies, the income from which help in the overhead. This hospital has been classified in class A by the American College of Surgeons for the last several years. The staff of this hospital consists of all the local doctors qualified to practice residing in the county.

According to the 1931 state directory, Yates County now has 22 licensed physicians, all of whom are members of the county society, except

three who were former members, but are now retired from active practice.

On December 21, 1926, this society adopted a fee bill which was sent to all insurance companies carrying compensation risks in the county, and as far as the committee can learn, they have all accepted these fees in settlement of all claims.

This fee bill has also been of great help since the enforcement of the new State Welfare Law in coming to terms with the County Commissioner of Public Welfare.

While, with few exceptions, the county society has not been consulted in the welfare work carried on in the county, in most cases, there are members of this society in the different organizations and they are active in mapping out their policies. In one case, your committee was informed that our only representative was a local optometrist.

G. H. LEADER, *Chairman.*

TRI-STATE MEDICAL CONFERENCE

The Nineteenth Tri-State Medical Conference met in the Hotel Chelsea, Atlantic City, N. J., on December 5, 1931, with Dr. John F. Hagerty of Newark, President of the Medical Society of New Jersey, presiding.

Those present from New York State were Dr. Thomas J. Harris, of New York City, who read a paper; Drs. Wm. H. Ross, J. E. Sadlier, and J. S. Lawrence.

The program consisted of three papers. The first was entitled "Looking at Both Sides of Our Public Relations," and was given by Dr. William Rowland Davies, of Scranton, Pa. Dr. Davies discussed economics, nursing and cults at considerable length, and his paper was discussed by nearly every physician present.

The second paper was entitled "Specialists and Specialism,—A Plan for Proper Control by State Societies," by Dr. Edward G. Waters, of Jersey City, N. J. Dr. Waters outlined a plan which

had already been presented before the New Jersey State Society and which was published in the Journal of the Medical Society of New Jersey of June, 1931; and in turn was abstracted in the NEW YORK STATE JOURNAL OF MEDICINE of July 15, 1931, page 928. This article indicates the trend of the paper.

The third paper was by Dr. Thomas J. Harris, of New York City, who discussed the attitude of the American College of Surgeons, the American College of Physicians, the American Society of Otolaryngologists, the American Gynecological Society and the Academy of Medicine to the certification of specialists and felt that progress was being made towards a solution of the problem, although he did not state what the probable outcome would be.

The next meeting of the Tri-State Conference will be held in New York in February.

CERTIFICATION OF SPECIALISTS IN OBSTETRICS AND GYNECOLOGY

The increasing amount of consideration given to the subject, "The Certification of Specialists," makes the announcement of the American Board of Obstetrics and Gynecology of interest to every physician. New York physicians will have an additional interest in the following announcement because the president of the board is Dr. Walter F. Dannreuther of New York City:

"The next written examination of the American Board of Obstetrics and Gynecology will be

held in nineteen different cities of the United States and Canada at 2 P.M. on Saturday, March 26, 1932. The general, oral and clinical examination will be held in New Orleans on Tuesday, May 10, 1932, immediately preceding the meeting of the American Medical Association. Reduced railroad fares will be available. For detailed information and application blanks apply to the Secretary, Dr. Paul Titus, 1015 Highland Building, Pittsburgh, Pennsylvania."

THE DAILY PRESS

Reg'lar Fellers

Not Easy to Remember

By Gene Byrnes

N. Y. Herald Tribune, January 4, 1932

MODERN ASTROLOGY

Astrology still flourishes in New York City and its practice is so profitable that a dealer in toys is suing a leading practitioner of the ancient mystery for \$25,000.00 for the alleged pirating of a chart showing the days which are favorable and those which are unfavorable. The makers issued the chart as a mere toy or game, but it was republished by an astrologer as a genuine article; and hence the law suit.

The New York *Herald Tribune* of January 8, describing the suit, commented as follows:

"In recent years, she has obtained, with her corps of assistant astrologers, almost a monopoly on the casting of horoscopes, her chief competitors having been wiped out by the general skepticism towards the science following the failure of any astrologer to make a public prediction of the World War or of the depression. She has made no public prediction of any kind since 1923 when,

on arriving here from Europe, she announced that President Harding and his Administrations were under happy auspices a few weeks before President Harding died and his Administration was involved in fearful scandals.

She tells in one of her books how she chose her husband through astrology. The Jordan horoscope proved that he was the perfect mate for her. She also has told how she selected her pet Pekinese through astrology. She would not buy even a goldfish without casting its horoscope. In an autobiographical volume she stated that she was wooed years ago by a British nobleman and was on the point of accepting him and settling down in his beautiful palazzo in Rome, but she was forced to reject him because on casting his horoscope she found that the nobleman's moon indicated that, if she married him, she would die early or prove unfaithful."

SPECIALISM IN MEDICINE

The inauguration of Dr. Frank L. Babbott, Jr., as president of the Long Island College of Medicine (the former Long Island College Hospital) in Brooklyn, on January 14, was described by the New York *Herald Tribune* of January 15. The *Herald Tribune* described the address by Dr. J. R. Angell, President of Yale University as follows:

"Dr. Angell criticized the specialization which concentrates too many physicians and surgeons in the metropolitan areas and leaves the less populated districts without adequate medical service. He pointed out that it was an ability to see the patient as an entity, coupled with a thorough

knowledge of his personal history, environment and background, that made the old-time country doctor a success.

"In these days of scientific knowledge of bacteria, surgery and the like, my statement may sound like a recrudescence of allegiance to the medicine man and faith healer," he said; "but at the least of the remedies carried by the country doctor of old was the confidence he inspired. Sooner or later modern medicine must recognize the intrinsic significance of these emotional and psychic factors in human health."

"Dr. Babbott in his installation speech said

BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.

MIDWINTER. By Ten Teachers, under the direction of CONYNS BERKELEY, M.A., M.D. Edited by CONYNS BERKELEY, J. S. FAIRBAIRN and CLIFFORD WHITE. Fourth edition. Octavo of 740 pages, illustrated. New York, William Wood & Company, 1931. Cloth, \$7.50.

MANUAL FOR THE JEWISH DIABETIC. By WILLIAM S. COLLENS, B.S., M.D. Octavo of 138 pages, illustrated. New York, Bloch Publishing Company, 1931. Cloth, \$2.00.

ALLERGY AND APPLIED IMMUNOLOGY. A Handbook for Physician and Patient, on Asthma, Hay Fever, Urticaria, Eczema, Migraine and Kindred Manifestations of Allergy. By WARREN T. VAUGHAN, M.D. Octavo of 359 pages, illustrated. St. Louis, The C. V. Mosby Company, 1931. Cloth, \$4.50.

LIVING THE LIVER DIET. By ELMER A. MINER, M.D. 12mo. of 106 pages. St. Louis, The C. V. Mosby Company, 1931. Cloth, \$1.50.

CONQUERING ARTHRITIS. By H. M. MARGOLIS, M.D. Octavo of 192 pages, illustrated. New York, The Macmillan Company, 1931. Cloth, \$2.00.

HEALTH CENTER DISTRICTS. New York City. Handbook. Statistical Reference data. Compiled by GODIAS J. DROLET and MARCQUERITE P. POTTER. Prepared under direction of ROBERT D. WIDEMER, Director, Committee on Neighborhood Health Development, Department of Health, City of New York. Second edition. Quarto of 59 pages, illustrated. (New York, Department of Health), 1931. Paper, \$1.00.

CERTIFIED MILK CONFERENCES held in 1931. Annual Conference American Association of Medical Milk Commissioners, Inc., and Certified Milk Producers Association of America, Inc., Philadelphia, June 8-9, 1931. Octavo of 334 pages. Cloth.

OUR NEIGHBORS

INCOME TAX COMPUTATION

The Journal of March 1, 1930 carried a brief note on deductions allowed in the Federal Income Tax, which was abstracted from the *Wisconsin Medical Journal* of January, 1930. The receipt of the thanks of several New York physicians for the suggestion in the abstract has led the editors to print an abstract of a somewhat similar article taken from the February number of the *Ohio State Medical Journal*. After giving the general provisions of the law, the Ohio Journal discusses the allowable deductions as follows:

"OFFICE RENTALS: If a physician pays rent to another person for office space, he may deduct the amount; if he owns his own home and maintains an office in it, he cannot claim deduction for office rent.

"AUTOMOBILE: The cost of repair and upkeep of an automobile used in professional visits may be deducted. That part of a salary paid to a chauffeur and attributable to time spent in driving his employer on professional calls, may be deducted. Sums spent for taxi hire, carfare, etc., while on professional calls, may be deducted.

"Loss on an automobile used in professional business through depreciation may be deducted. The depreciation which should be deducted annually is figured by dividing the cost price of the machine by the number of years of its usefulness.

"If a physician has one automobile which is used exclusively in professional business, he may deduct the full depreciation each year. If the machine is used only partly in professional business, the deductible depreciation should be computed on the basis of the amount of time the car is used for professional purposes.

"If a physician possesses two cars, each of which is used partly in professional business, the deductible depreciation on each car should be computed on the basis of the amount of time each car is used for professional purposes.

"In other words, if an automobile is used only partly for business purposes, depreciation may be deducted only on a proportionate part thereof, the amount of depreciation depending on the amount of time the machine is used in professional business.

"PROFESSIONAL DUES: Dues paid to professional associates to which, in the interest of his profession the physician belongs, are exempt and may be deducted. Travelling expenses incurred in attending medical conventions of organizations of which he is a member are deductible from gross income in determining net income derived from

practice. Expenses incurred in taking graduate courses have been held NOT to be deductible.

"ASSISTANTS: Deductions are permitted for the salaries of nurses, laboratory workers, technicians, assistants, stenographers or other clerical workers in offices so long as their duties are connected with professional work. Wages paid maids for services rendered in connection with practice are deductible.

"MEDICINE, INSTRUMENTS, SUPPLIES: Medicines used in the office to treat patients, medicine dispensed, bandages, laboratory materials and all other supplies necessary to operate the office may be deducted. Upon surgical instruments, one-fifth of purchase price may be deducted annually for five years under depreciation account. All office fixtures, appliances, etc., used in office or laboratory may be depreciated annually, according to the estimated life of their usefulness.

"GENERAL OFFICE EXPENSE: Cost of telephone, telegrams, etc., used in professional services may be deducted. Expenditures for heat, light, water, etc., are deductible. Office fixtures and furnishings may be depreciated 10 per cent annually. Original cost of medical books may be depreciated 10 per cent annually, since the life of these is usually considered 10 years.

"WHEN TO DEDUCT DEBTS: If the physician's books are kept according to the 'Cash Receipts and Disbursement' system, he may not charge off any unpaid debt because he is then only reporting as gross income those accounts which have proved to be good. Bad accounts have not been reported and are therefore, not deductible.

"If books are kept on an 'Accrual Basis' (where expense is actually incurred and payable even though not yet paid, or income earned although not yet collected) it is permissible to charge off all debts which have been definitely ascertained to be worthless during the fiscal year covered by the report.

"In the same way, the physician is permitted to claim deduction for all other expenses within the scope of his profession, and the amount of his tax is determined on the net income which remains after these items have been deducted.

"TAXES AND LICENSES: Any tax paid upon materials required in professional work are exempt. All license fees which physicians are required to pay are deductible items. This includes the narcotic tax, automobile license, local occupational taxes, taxes on club dues, etc. The Ohio Gasoline Tax is not deductible.

A new SQUIBB Glandular Product

FOLLUTEIN

ANTERIOR PITUITARY SEX HORMONES

NOW AVAILABLE

This illustrated booklet has been prepared to help physicians keep informed about the progress made in the study of the sex hormones. It contains a complete description of the relation between the sex hormones and menstruation and describes the physiology and clinical application of the estrus-inducing (follicular) hormone.

The object of the booklet is to stimulate increasing interest in Amniotin—a physiologically tested, highly stable preparation of the estrus-inducing (ovarian follicular) hormone.

Requests for literature should be addressed to Professional Service Department, E. R. Squibb & Sons, 745 Fifth Avenue, New York.

Follutein is a physiologically tested solution of the anterior pituitary sex hormones prepared from urine of pregnant women by a modification of the Zondek-Aschheim method. It is used in the treatment of infantilism, amenorrhea, menorrhagia, sterility and threatened abortion.

It stimulates the production of graafian follicles, induces ovulation, develops corpora lutea and secondary sex characteristics.

It is free from proteins, fats, phospholipins and the growth-promoting hormone.

Follutein is supplied in sterile, aqueous solution for subcutaneous injection, in 5 cc. vials containing 50 Zondek-Aschheim units per cc. Because it is stable for only five or six weeks it will not be carried in stock by druggists, nor can it be returned for exchange or credit. All sales on this product are final and shipment is made with that understanding. Ask your druggist to order it for you.

NOTE: Because of limited production, samples of Follutein cannot be supplied

RECLAIMING the DRINKER

By

CHARLES B. TOWNS

*Pioneer in Development of
Towns Method of
Treatment for Addictions*

The Alcoholic, being essentially a medical problem physicians will find valuable help in this book which records the observations of Mr. Towns in dealing with alcoholics for over thirty years. RECLAIMING THE DRINKER, includes quotations from noted physiologists, hygienists and laboratory investigators. It discusses various aspects of alcoholic insanity. It reflects a sympathetic and intelligent understanding of the physiological, the psychological and the human problems involved in the rehabilitation of the alcoholic.

CONTENTS

Why Men Drink. When is a Man Drunk?
The Mental Effects of Alcohol
Alcohol As a Deteriorator
What Animal Experimentation Proves
Is Alcohol a Food?
The Truth About Beer
Prevention of Alcoholic Insanity
Reclaiming the Drinker

*To any physician especially interested
in the alcoholic-narcotic problem, a copy
will be sent with the author's compli-
ments*

(Continued from page 238)

"LOSSES BY FIRE AND THEFT: Loss of and damage to a physician's equipment by fire, theft, or other cause, not compensable by insurance or otherwise recoverable, may be computed as a business expense, and is deductible, provided evidence of such loss or damage can be produced. Such loss or damage is deductible, however, only to the extent to which it has not been made good by repair and the cost of the repair claimed as a deduction.

"INSURANCE PREMIUMS: Premiums paid for insurance against professional losses are deductible. This includes insurance against damages for alleged malpractice, against liability for injuries by a physician's automobile while in use for professional purposes, and against loss from theft of professional equipment, and damage to or loss of professional equipment by fire or otherwise.

"LEGAL EXPENSE: Expense incurred in the defense of a suit for alleged malpractice is deductible as business expense. However, expenses incurred in the defense of a criminal action are NOT deductible.

"OTHER ALLOWABLE DEDUCTIONS: All taxes paid upon real or personal property, whether the property is used for business or otherwise and all interest paid upon indebtedness (except interest paid to carry nontaxable securities) are deductible. It is permissible to deduct from gross income, contributions when made to charitable, religious, education and scientific organizations, to an amount not to exceed 15 per cent of the net income, exclusive of such contributions.

"ITEMS NOT REPORTABLE AS INCOME: Allowances received under the War Risk Insurance act; bequests; damages received in personal action; dividends on stock of federal reserve banks, land banks and intermediate credit banks; dividends from exempted building and loan associations up to \$300; dividends from corporate earning accumulated prior to March 1, 1913; gifts, inheritances, insurance proceeds; state court jury fees, state court receivership fees, life insurance proceeds, and stock dividends and rights, are not reportable as income.

"All interest received from obligations of a state or political subdivision thereof; from securities issued under the Farm Loan act; interest on Liberty 3½% Bonds and U. S. Bonds issued prior to September 1, 1917, and interest on the obligations of the possessions of the U. S. need not be included in the computation of gross income.

"Interest received on Liberty 4% and 4½% Bonds and certain other U.S. obligations is exempt if the total holdings are not in excess of \$5,000. All interest received on U. S. Treasury notes must be reported. However, all interest received from these sources which is reportable as income, is subject only to surtax."

ANNUAL MEETING IN OREGON

The January number of *Northwest Medicine* contains the minutes of the annual meeting of the Oregon State Medical Society held October 22-24, 1931. Dr. F. D. Stricker, Secretary, reported on malpractice insurance rates as follows:

"The question of employing attorneys for members who were insured by insurance companies against liability from malpractice suits was considered and it was decided that these members were entitled to legal service from the medical defense fund of the Society, if they made a request for such service. However, it was found that most members of the Society were insured for liability insurance by regular indemnity insurance companies. This made it advisable to secure data by which the entire membership of the Society could be so protected. Rates were obtained from a reliable insurance company whereby the following reduced rates would be possible:

"\$ 5,000-\$15,000	\$12.00
"\$10,000-\$25,000	\$16.00

"The proposal was made to pay these premiums by paying three dollars out of the present medical defense fund, three dollars out of the current dues and to assess the balance to the individual members' dues. This proposal is to be submitted to the House of Delegates for action."

The Executive Secretary made the following report on a cooperative business bureau:

"During the past two years, our state medical society has worked out the so-called 'Oregon Plan' under which the local medical society, in cooperation with the local dental and graduate nurses' associations and the hospitals, maintains a cooperative business bureau. Bureaus of this type are in operation in Portland, Salem and Eugene.

"These bureaus have contributed greatly toward improving the methods of caring for the business side of medical care. Delinquent accounts are collected on an actual cost basis and a centralized file of credit information has been developed in each of these communities. Owing to the financial depression, efforts to extend this type of service to all parts of the state have been delayed. Steps were taken, however, to place the facilities of the Portland bureau at the disposal of the physicians of a number of nearby communities, including Clackamas, Yamhill, Washington and Columbia counties.

"During the year, also, a suggested uniform business procedure for physicians, including uniform office record forms and monthly statements, was prepared and made available to the membership. It is believed that the adoption by physicians generally of a uniform approach to the patient in matters relating to the financial aspects of medical care would have a stimulating effect toward educating the public to recognize its obligation to pay the doctor promptly and adequately."

(Continued on page 242—Adv. xvi)

Dear Doctor You may not specify any special brand of Cod Liver Oil when you prescribe it for your patients. Probably most doctors do not.

Yet you want your patients to have the factors which you know Cod Liver Oil contains—Vitamins A and D.

As you know, different Cod Liver Oils contain these health giving Vitamins in varying amounts. It is therefore important to give an oil of known high Vitamin content.

You will we believe be glad to know these facts about Puretest Cod Liver Oil. Every lot of Puretest is tested for Vitamin potency. It contains not less than 50,000 U.S.P. Vitamin A Units in each 100 grams, and not less than 13,333 Oslo Vitamin D Units in each 100 grams. And this high Vitamin potency is always uniform and stable because Puretest Cod Liver Oil is protected from deterioration by air by means of filling containers with Nitrogen gas. Don't you think these standards are worth considering?

Puretest Cod Liver Oil is obtainable at all Rexall and Liggett Drug Stores

(Continued from page 241—Adv. xv)

Publicity work included a speakers bureau health news stories, fair exhibits and radio broadcasts. Public reading rooms were described as follows:

"Each of the three component societies which have established permanent headquarters (at Portland, Salem and Eugene) has been assisted in maintaining a public reading room and health information bureau stocked with an excellent supply of health pamphlets and posters of special interest to the lay public. Attractive window displays of health materials are also a feature of these educational efforts. The popularity of this type of activity is attested to by the fact that approximately 20,000 persons made use of the reading rooms during the past year."

Legislative matters were discussed as follows:

"A basic science act was carefully drawn and its introduction by Senators Booth and Upton arranged for. The bill received more public and newspaper support than at any previous time and after a bitter fight was lost in the Senate by only two votes. The Woman's Auxiliary was of great assistance in organizing the support of numerous prominent club women who appeared before the

Committee on Medicine, Pharmacy and Dentistry in behalf of the bill. Cooperation was also given the hospitals of the state in securing the passage of the hospital lien law. The defensive strength of the health forces in the legislature was shown by the successful fight on the numerous cult bills, including the measure proposing to create a department of osteopathy at the University of Oregon Medical School, the bill to permit chiropractors and naturopaths to treat patients in the hospitals, and the measure proposing to compel the State Industrial Accident Commission to allow chiropractors and naturopaths to care for industrial accident cases."

Comment was made on the standing of the scientific articles in *Northwest Medicine*:

"*Northwest Medicine* is maintaining the high standard it has set for itself. This is shown particularly in the reviews of abstracted literature.

"In the last issue of the Year Book of Surgery of the Practical Medicine Series, *Northwest Medicine* was quoted ten times, this being an average of almost one abstract from each issue during the year. It ranked right near the top in this regard among the twenty-one state journals abstracted, many of which had but one reference."

More Than Just a Mere "COMBINATION"

Every Camp combination has as its foundation an inner belt which is a true Camp Support, embodying the Camp Patented Adjustment that provides the maximum benefit to be derived from this type of garment.

Model No. 3160, illustrated, is recommended for post operative and general wear, slight organic displacement, control of fleshy deposits on the abdominal walls, or restoration of normal conditions following pregnancy—also for normal wear.

Only CAMP Has This Feature

The Camp Patented Adjustment is an exclusive, non-competitive feature. The continuous lace running through the adjustment straps (and not affixed to them), as well as through the garment itself, automatically balances the adjustments to fit individual conditions.

Sold in Drug and Department Stores, Surgical Section, Surgical Houses, and Corset Specialty Shops.

PUBLIC RELATIONS IN IOWA

Many State Societies have Committees on Public Relations but these committees are diverse in the scope of their activities. The January issue of the Journal of the Iowa State Medical Society suggests that the Society form such a committee, whose duties should be as follows:

- 1 Caring for business problems, effecting commercial and lay contacts
- 2 Coordinating lay and scientific activities
- 3 Molding thought and leading auxiliary health movements
- 4 Directing publicity and educational campaigns for the profession and the public
- 5 Sponsoring and censuring general and special articles of news value
- 6 Providing editorials
- 7 Outlining programs for the press and county units
- 8 Directing business service and research in new methods of doing and obtaining business and the best methods of dealing with other economic problems of interest to the doctors of the association
- 9 Supplying the doctors and committees with information relative to the fitness of the respective candidates for public office with special reference as to how they would vote on matters of public health
- 10 Investigating and advising in all matters submitted to the legislature
- 11 Directing the legal aspect of business procedure of the association and doctors
- 12 Furnishing information concerning mal practice, systems of collections, as well as special information for the members, upon request

The Iowa State Medical Society already has the following standing committees:

- 1 Medico Legal
- 2 Scientific Work
- 3 Public Policy and Legislation
- 4 Constitution and By-Laws
- 5 Publication
- 6 Finance
- 7 Arrangements

The State Society also has the following special committees:

- 1 Historical
- 2 Economics
- 3 Library
- 4 Military Affairs
- 5 Nurses Training
- 6 Speakers' Bureau
- 7 Superannuated Physicians
- 8 Women's Auxiliary
- 9 Child Health

It would seem that a large part of the field of the proposed public relations committee is already covered by other committees.

OSTEOPATH CLINIC IN DELAWARE CHURCH

The December issue of the *Delaware State Medical Journal* has the following editorial comments on an osteopathic clinic run by a church:

"St. Paul's Methodist Episcopal Church, of Wilmington, provides a clinic for treatment of disease by osteopaths. According to the daily papers specialists of eye, ear, x-ray, proctology, etc., are there to treat special as well as general diseases. Osteopathy as officially defined by the American Osteopathic Association is 'that system of the healing art which places the chief emphasis on the structural integrity of the body mechanism, as being the most important single factor to maintain the well-being of the organism in health and disease.' The Pennsylvania law relating to the practice of osteopathy specifies that license to practice as an osteopathic physician 'shall not authorize the holder thereof to practice operative surgery without obtaining an additional license to practice such surgery, as provided in section eleven (b) of this Act.'

"Are these doctors qualified to do this work as stated in the public press? What training have they had in the various special branches? Have those who are responsible for this clinic investigated, and are they capable of judging? Are any of their surgeons members of the American Surgical Association or the American College of Surgeons? Has any one passed any special national board such as the American Board of Ophthalmology, or Otolaryngology, or Gynecology and Obstetrics? If they have, and are qualified, all well and good. If they are not competent to care for all these poor unfortunate patients who go to this clinic, with the assurance that any condition or complication they may have will be cared for by experts, then the officials of St. Paul's, or whoever may be responsible for such a state of affairs, may have some serious retributions to answer for when they pass across to the Great Beyond.

"But why have medical clinics, sponsored by laymen and run by cultists at all, when there are in the community regular hospitals expensively equipped for all kinds of medical and surgical examinations and care? Would it not be better for laymen to give their aid to such institutions instead of establishing so-called clinics hither and thither, which are not only very apt to be inefficient, but most likely to be bad medically, sociologically and economically? This question is especially pertinent when one realizes that these regular clinics are prepared to give correct diagnosis and efficient treatment, regardless of the social or economic status of the patient."

ECONOMICS IN PENNSYLVANIA

The January number of the Pennsylvania Medical Journal contains an account of a meeting of the Lycoming County Medical Society on December 11, at which a bank official gave some excellent financial advice as follows:—

"Mr. Charles A. Schreyer of the local Lycoming Trust Company, gave an address entitled 'Investing from the Professional Man's Point of View.' He discussed the fundamental principles of investment, and confined his remarks to investments other than one's home, other real estate, or insurance. He said in part that the doctor should always have a steady income apart from investments; that stocks, bonds, and mortgages should represent a reserve fund. He advised that the average physician should invest only in the higher sort of securities not requiring close observation and to avoid those classed as speculative. He explained that investment plans of twenty years ago would not apply today since many securities considered gilt edge then are considered poor today. The comparative merits of common and preferred stock were dealt with and he informed us of the plan advised by certain reliable banking firms. First, major investment should be in gilt edge securities in the sound basic industries. The modern belief is that the following proportions are sound; 20 per cent in good bonds; 50 per cent in mortgages; and 30 per cent in reliable stocks.

"The average price of a good bond 10 years ago was \$78.20, whereas in October, 1931, it was \$100.50. A diversity of holdings is desirable, in that some fluctuate adversely, which yields a steady income under all conditions.

"The average yield of the highest grade bond is 4.92 per cent; next highest grade, 5.28 per cent; and of some sound bonds 6 1/2 per cent. The current yield on United States government bonds is 3 1/2 per cent, a good rule being that any bond yield of over twice that of the Government bond is apt to throw it into the speculative class and therefore risky. In fact anything over 5 1/4 per cent is risky. First mortgages are good if ready market ability is not required, and mortgage certificates yielding 5 per cent make a good backlog. Among those investments recommended were telephone, and sound public utilities, such as P. P. & L. Railroads' stock not recommended at present. Securities should be bought only through the most reputable firms to be advised by the bank. He did not recommend the purchase of common stock by physicians."

"WHAT A PLEASANT WAY TO GET
BACK MY STRENGTH, DOCTOR"

Extra nourishment

without extra burden on the digestion

DOCTORS often say that, in convalescence, one of the greatest problems is nutrition. Yet it is as frequently necessary to persuade the patient as it is to fight the condition.

It is quick digests milk, those who etite, yield to the delicious chocolate flavor of Cocomalt.

Far more important, however, Cocomalt actually adds 70% to the nutritive value of every glass or cup of milk. For Cocomalt is a scientifically balanced combination of milk proteins, milk minerals, cocoa, eggs, barley malt and sugar.

is an old law, but it was stated that in some towns the legal requirement is still carried out when it seems desirable. One of the speakers stated that while cards are useful, the man whose house is carded may, if he wishes, tear up the card and the board of health has no redress. Another speaker voiced the principle, that if the board is likely to go to the courts in the matter of a quarantine, it will be well to attend to the required detail of the red flag. Mr. W. G. Kirschbaum of New Bedford, stated that he had been to all of the Massachusetts state health commissioners from the time of Dr. McLaughlin, in attempts to have the law so changed that cards would be legal, but thus far without legislative result.

"The matter of notification of cases by physicians was subject to a long discussion. The first question was that of notification by telephone. The law was quoted as requiring this notification in writing, but in these days, in many places, the telephone is used almost exclusively. In New Bedford a card record is made of the telephone information, and when the board of health physician visits the house other cards for contacts and other persons are made, and the office record is thus complete. In some smaller places there is not a constant service, and the telephone does not

prove so satisfactory. Mr. Hallett noted that here there is a difference in procedure between large and small places.

"Dumping grounds and nuisances were other matters discussed. With reference to the first, the law places the care of such with the boards of health. The nuisance seems to be a very uncertain matter, because litter and smells do not always constitute a menace to health, hence the boards may be puzzled as to whether a 'legal' nuisance exists."

ANNUAL MEETING IN MAINE

The January issue of the *Maine Medical Journal* comments on the annual meeting of the Maine Medical Association to be held June 16-18, 1932. Concerning the scientific program it says:

"The program as adopted for this year will be considerably different from previous years. It will cover two and a half days instead of two full days, as formerly, closing at noon on Saturday. The two afternoon sessions and the closing session Saturday morning will be given over to papers, while the two morning sessions, Thursday and

Friday, will be devoted to a series of group round-table conferences, covering a variety of subjects.

"The papers will be about twelve in number, four to a session. All the papers will be of general interest, based upon some phase of diagnosis and aimed to assist the general practitioner in a practical manner.

"It is felt that this system, which has proven so popular and worthwhile in some of the national societies, will fulfil a long-felt want in our association. Everyone will find something in which he is vitally interested and will be able to discuss it with others similarly interested. A complete list of the conferences will soon be announced in the Journal. Applications for each conference can be made to the committee and will be filled in order of their receipt."

PUBLIC RELATIONS IN CALIFORNIA

California and Western Medicine of January contains the following note regarding the administration of public relations of the State Society:

"The Department of Public Relations of the California Medical Association has had two meetings and the organization is now complete. It is ready for work. The problems before it are many and varied, and involve a complex picture of economics, social adjustments, and legislation.

"The members of the committee have canvassed the Association for a man to act as a director of their newly formed department. According to the resolution, this man must be a doctor. However, there are many other prerequisites for this man. He must be a good speaker as well as a good fellow. He must be a good organizer. He must be a man who has studied, and knows, the problems of medical economics. He must be a statistician, and know how to evaluate statistics. He must be a publicity man, and understand how to organize publicity. He must be a politician, and be able to follow legislative measures in our legislature, as well as organize the medical profession in legislative matters.

"And, above all, he must be a man who is willing to act in accordance with the decisions and will of the Council of the California Medical Association and the Public Relations Committee.

"Thus far, the committee have been unable to find this man, but they are not discouraged and they feel that there is such a man in our society who can take up the reins and act as the executive officer in a fulltime position with the California Medical Association."

The Thoroughbred OF PSYLLIUM SEEDS

WHEN you prescribe psyllium seed make sure it is a variety that measures up to your ideas of cleanliness and wholesomeness.

Psyllium seed as it comes from the producers abroad is grievously contaminated with waste material that is not fit for human use.

You can have the utmost confidence, however, in prescribing

PSYLLA
(Plantago Psyllium)

This is not the ordinary commercial seed, but a highly refined product which has been subjected to a most efficient cleansing process, including screening, sifting and fanning. In this way the dead, shriveled up seed is removed, as well as half a dozen kinds of waste material which should never enter the stomach.

NOTE: Psylla is sterilized. There is an inner seal on each can which is a guaranty of its wholesomeness.

when dyspeptics beg for quick

In functional dyspepsia and gastric neuroses, quick symptomatic relief is afforded by the digestant and sedative Pancreobismuth and Pepsin. And whenever there is insufficient or faulty digestion from any cause, Pancreobismuth will help to supply the needed digestive enzymes.

Pancreatin, pepsin and taka-diasase* provide for digestion of protein, fat and carbohydrate. Bismuth subnitrate allays gastric and intestinal irritation.

Sodium bicarbonate supplies antacid. And powdered ginger is stomachic and carminative.

This tried formula will serve you well for relieving sudden attacks of dyspepsia due to dietary indiscretion and also the more protracted types of gastric or intestinal disorder when the physiological secretions are deficient.

Prescribe $\frac{1}{2}$ to 1 teaspoonful in a wine-glassful of lukewarm water after meals.

*Uniform in composition and 2 to 6 times more potent than ordinary malt diastase

JOURNAL OF DISTRICT OF COLUMBIA

The Medical Society of the District of Columbia has established its own monthly journal, called *Medical Annals*, beginning with the January issue. This journal takes the place of its annual volume of transactions, and also of the defunct *Washington Medical Annals*. Its immediate predecessor was a monthly bulletin of the society, which was expanded into the present journal. The aims of the journal are set forth in the following editorial:

"The year 1932 marks the birth of this publication. The *Annals* replaces the Bulletin but is really a continuation of the *Washington Medical Annals*, coming back to life after a period of eleven years.

"The contents of the *Annals* will be somewhat as follows:

- "1. Selected papers and abstracts of papers presented before the Medical Society.
- "2. Reviews of various subjects and reports of recent advances in medicine, surgery and the specialties, to be designated 'Science Series.'
- "3. Transactions of special sections of the society.
- "4. Editorials.
- "5. News of activities of organized medicine throughout the world.
- "6. Report of accomplishments of interest from local medical schools, hospitals, and government institutions, and also from the various smaller local societies.
- "7. Activities of committees and also individual members of the society of general interest."

DISCUSSING PAPERS IN COLORADO

Dr. Earle Whedon, the editor of the Wyoming Section of *Colorado Medicine* for November, commends the scientific meeting of the Colorado State Society, as follows:—

"It was the privilege of Ye Editor to attend the Colorado Medical Society, September 15, 16, and 17. There were several outstanding things in these days spent so delightfully.

"The members talk like gentlemen when reading and discussing the scientific papers. Ye Editor has been present in Colorado State Medical Society meetings when he thought those who discussed the carefully prepared papers were auto mechanics, their only desire being to tear out the rear ends of the authors who presented the papers. This year it was different. Those who discussed the papers—as we said above—talked like gentlemen. Really, it was fine."

NEW YORK STATE JOURNAL of MEDICINE

NEW YORK, N. Y.

MARCH 1, 1932

ACUTE GLANDERS IN MAN. A CASE REPORT

By LLOYD I. ROSS, M.D., and R. LOMAX WELLS, M.D., NEW YORK, N. Y.

From Medical Division A, St. Luke's Hospital, New York, Dr. H. S. Patterson, Director

WITH the constant advance in the understanding of disease aided by increasing and efficient public health measures, many diseases have reached comparatively low levels of incidence, and others have come to be classed as rare. Among the latter we find glanders. In New York City the decrease in glanders is shown in the following table of figures on the total number of cases reported yearly to the Board of Health since 1920:

1920.....	71	1926.....	4
1921.....	75	1927.....	1
1922.....	117	1928.....	1
1923.....	43	1929.....	12
1924.....	100	1930.....	0
1925.....	8		

Interest in the case of infection with *B. mallei* in man here reported centers in its occurrence in a thickly populated district as an isolated case and at a time when the disease is rarely considered in differential diagnosis. The identity of the disease process was not suspected during the course of the disease and was not proved until after the death of the patient. After the existence of *B. mallei* infection had been proved by bacteriological and serological studies, an effort was made to locate any contact that the patient may have had with stables, horses, etc.—a point not considered or elicited in the history on admission. It was discovered that the patient was a great lover of horses and was a frequent visitor at a stable in New Jersey where he kept a horse. About two months previous to the onset of the patient's illness his horse had died following a short illness characterized by profuse mucous nasal discharge and cervical glandular enlargement, the diagnosis of influenza having been made by the veterinarian. Previous to this another horse in the same stable had died of "pneumonia." It was our feeling that the patient had harbored the glanders organisms in his upper respiratory tract and that the extraction of teeth two days prior to admission had furnished the point of lowered resistance in

which the organisms gained a foothold, multiplied, and spread.

In view of the original diagnosis of acute fibrinous pleurisy in the case here reported it is of interest to note that Meyer and Crohn¹ in 1908 write: "In reviewing the literature one is struck by the failure in making even a tentative diagnosis of glanders in the early stages of the disease. The diagnoses most frequently made are pleurisy, acute articular rheumatism or typhoid fever." They attribute this to the late appearance of the eruption.

Furthermore, in view of the positive blood culture in our case, we note with interest that Crohn² reported fourteen cases from the literature in 1909 with eleven positive and three negative blood cultures. Blood cultures taken early in the course of the disease were negative as were those in chronic cases. The positive cultures were reported late in the disease. The duration of the acute cases varied from 11-36 days and were invariably fatal. In 80% of the cases initial symptoms were referable to the lungs.

We present this case to remind the physician that glanders despite its decreasing rate of incidence must still be considered in his differential diagnosis in cases of sepsis with symptoms of pulmonary disease and abscess-like lesions of the skin.

Patient: F. D.

Admitted to St. Luke's Hospital on March 28, 1931.

Died April 8, 1931.

Past History: Born in Holland, patient came to U. S. A. in 1910. For the past 9 years has worked as a tester for the N. Y. Telephone Co. Father and mother died of pneumonia complicating influenza. Family history irrelevant. While serving overseas, he was gassed with chlorine and suffered from "shell shock." Since then he has had occasional sore throats, and this winter he has suffered with colds.

Two days before admission patient had had three teeth extracted. At 6 P.M. on March 27,

1931, as he was going to work, the patient was seized with an intense pain in the left lower chest, posteriorly, near the spine. The pain was increased on deep inspiration, or motion. No cough, chill, sweat, sore throat or headache. No nausea or vomiting. Appetite good. Bowels regular. The pain continued to increase and patient came to the hospital at 3 A.M., March 28th, and was admitted to medical ward.

On admission, physical examination showed: "A well developed, well nourished white man of 37, complaining of pain in left posterior chest. Head: No mastoid or sinus tenderness. Eyes: Pupils equal and regular, react rather slowly to light. Ocular movements normal. Ears and nose normal externally. Mouth: Tonsils small, teeth in poor condition. Upper right first and third molars recently removed with blood clots in tooth beds. Pharynx negative. Neck: No adenopathy. Chest: Symmetrical, both sides move freely and equally, with respiration, but patient complains of pain on deep inspiration. Lungs are resonant throughout. Normal voice and breath sounds. No rales or friction rubs heard. Blood pressure 108/65. Abdomen soft, no tenderness. No masses or organs felt. No scars or herniæ. Genitalia normal. Extremities negative. Reflexes: Knee jerks and ankle jerks active and equal. No abnormal reflexes. Impression: Fibrinous pleurisy (?)"

The admission temperature was 99.4. Pulse 96. Respirations 24. X-ray reports showed 4 molars in the upper left jaw and absorption around the roots of the first bicuspid and first molar. The remaining teeth in the upper jaw and all the teeth in the lower jaw appeared normal. There was marked thickening of the antra and ethmoidal sinuses. The heart, diaphragm and aorta appeared normal. Some thickening in the lower inner zones of the lung fields but no evidence of definite consolidation.

The urine was normal. The Wassermann was negative. The blood count showed hæmoglobin 99 per cent, red blood cells 4,900,000, neutrophils 67 per cent, lymphocytes 32 per cent, basophils 1 per cent.

The temperature rose to 102 the afternoon of admission, and spiked to 104.2 by March 31st. It remained spiking between 102 and 104 till April 6th, after which it remained at 104, and then went to 105 on April 8, the day the patient died. On March 30th, at 4 P.M. the patient complained of pain in the left side of his face and also a stiff neck. The next morning he had a headache and by noon the pain in the left side of the face was very severe. The patient was examined by the otologists, who decided that the pain was reflex from the throat. Blood culture of March 31st showed no growth. April 1st, the headache and face pain persisted, very severe. The throat seemed inflamed and was cultured, a

few fusiform bacilli and spirochetes were seen in the smear, and the culture was negative for diphtheria. Patient had severe pain in the back of his head. April 2nd: Profuse diaphoresis. Intense pain across forehead and down left side of face. Cannot seem to get his tongue out of his mouth at all. Extreme pain on left side of face, which is markedly swollen, when side of mouth is touched, causing twitching of face. Blood urea 25 mg., sugar 125 mg. April 4th: Both tonsils red and swollen, left more than right. Gums in bad shape. "Left tonsil might break down and form abscess." Nose negative. Impression: "Vincent's Angina of tonsils and gums or beginning left peritonsillar abscess." Salvarsan and 5% glucose to gums, 1000 c.c. infusion of 5% glucose. April 5th: Patient had difficulty in swallowing. Nose and throat consultant advised lancing peritonsillar abscess. Incision made in left peritonsillar region, but no pus obtained. Six-thirty P.M.: Patient unable to speak intelligibly, in much pain, mentally dull. April 6th: White blood cells 3,800. Neutrophils 80%. Lymphocytes 20%. Hardly able to open his mouth, much difficulty in swallowing. Patient taken to operating room. "There was a brawny necrotic induration involving the major portion of the soft palate, extending over in the left tonsillar fossa" which was incised with a cruciate incision and was found "to contain a small amount of necrotic granular base from which a culture was taken." This showed streptococcus hemolyticus and streptococcus viridans. The pathological report showed "acute suppurative inflammation." April 7th: Patient definitely worse, despite clysis, infusion, and transfusion. Induration of left cheek and temporal region more marked. No area of fluctuation. In center of area there have now appeared several small pustules. April 8th: Progressively worse. Face and arms now covered with pustular papules. Temperature from 104.4 to 105.2. Urine shows very faint trace of albumin, rare hyaline and granular casts. Blood culture taken. Consultant from Board of Health saw case and said it was not smallpox but possibly a staphylococcus pyemia. Patient died at 10:40 P.M.

Autopsy No. 2999: ". . . There is a massive swelling of the left side of the face with ulcerated area with raised edge 2 cm. in diameter in the preauricular region. There is a similar ulceration over the zygoma and one on the lobe of the ear. Scattered over the skin of the face, neck, trunk and extremities there are discrete raised lesions each about 1 cm. in diameter. Some of these are vesicular, others pustular, still others umbilicated. A few smaller ones appear as nodules. No free fluid is in either pleural cavity. Both lungs are free. The pleura is smooth but studded with small, firm, raised areas, some of which are white, others purple. On section these

are seen to be minute abscesses, the purple ones resemble infarcts with a necrotic center. There are also numerous similar abscesses throughout the parenchyma of the lung. There is an ulceration 3x4 cm at the base of the tongue on the left side. The tissues of the left side of the mouth and pharynx are necrotic. There are small collections of pus in the epiglottis and upper part of the trachea. The tongue and larynx appear normal."

May 4th Report of blood culture taken on April 8th shows *B. mallei* in both the broth and the plates. Culture from pustule of the skin, April 8th, shows *B. mallei*.

These findings have been checked by cooperation of the Board of Health.

After the autopsy had been performed and the blood culture had been found to be positive, showing a Gram negative bacillus which morphologically and culturally was characteristic of *B. mallei*, an investigation was begun into the history of the patient with regard to possible contact with horses. This investigation revealed the fact that the patient had been an ardent horseman all his life, had been accustomed to ride three or four times a week and owned his own horse which he kept in a stable in New Jersey. This

horse had developed a cold during February with a profuse mucoid discharge from the nose and mouth with palpable glands in the neck. The horse had subsequently died about three weeks prior to the patient's admission to the hospital, the veterinarian's diagnosis being influenza pneumonia. So far as could be ascertained only one other horse in the stable had been ill, and this horse had an illness similar to the above and died of so called influenza pneumonia about a month prior to the death of the patient's horse. The owner of the stable and the veterinarian were both consulted with regard to the possibility of glanders, but seemed reluctant to discuss the matter and gave very little information, all of which would be of questionable value as to its truth. It seems reasonably certain that the two horses in this stable were afflicted with glanders and died of that disease rather than of influenza pneumonia. Presumably the patient, who was in constant contact with his horse during its illness, received his infection at that time.

PLASTIC SURGERY, ITS USES AND LIMITATIONS

By CLARENCE R. STRAATSMA, M.D., NEW YORK, N. Y.

I HAVE chosen to talk to you on the uses and limitations of plastic surgery because I feel that it is well to know the extent of any branch of surgery and because there still exists in the minds of many professional men some doubt as to the indications for it.

The last war gave a new impetus to reconstructive surgery and many possibilities which had previously remained dormant developed at that time. After the war new fields for service in our everyday life were opened up. Congenital deformities,—such as hare lip, cleft palate, ear malformations, web fingers, etc.—and acquired ones,—such as noma, osteomyelitis of the jaw, scarlet fever with its resultant mouth and facial infections, diphtheria, causing stenosis of the pharynx, and trauma,—all require certain types of reparative surgery.

For centuries all surgeons have done a certain amount of reconstructive surgery, including rhinoplasty, repair of cystocele and rectocele, but it has always been the specific aim of men doing surgery of the head and neck to leave as little scar as possible. Nevertheless, the primary

endeavor is to restore the function, for authorities have found that if the function of the affected part is restored, the cosmetic result will quite likely be satisfactory. It must be remembered that the word "functional" may be applied to the repair of the mouth, a portion of which may have been removed in the treatment of cancer, or because of trauma, to a finger or arm which may have been rendered useless because of contractures, which require both the excision of the scars and the covering of the defect by grafts of one type or another, or to patients having limited motion of the neck with inability to lift the chin because of severe scarring which in some instances actually fastens the chin to the chest.

In the plastic clinics of the New York Post-Graduate Hospital and the New York Eye and Ear Infirmary we see from time to time all types of cases needing such surgery—for example, paralysis of the face due to injury of the seventh nerve during a mastoid operation, ectropion of the eyelids due to fire or acid burns, or to accident, atresia or partial atresia of the nostrils, partial loss of the cheek or lip, contractures of the neck, partial loss of the buccal sulcus, so that plates cannot be fitted properly, depressed scars, with

* Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse N. Y. June 2, 1931.

adhesions limiting the motion of the parts involved. It is a known fact that an individual who has had open sores with constant irritation for a period of years, may develop cancer. In such cases timely repair of an ulcer will then prevent malignancy. X-ray and radium burns very frequently produce open lesions which require plastic work. These cases need plastic surgery to restore the function as well as the cosmetic condition.

We also see the type of case which needs repair entirely from the cosmetic standpoint. This phase of reparative surgery is done to alleviate or remedy illnesses which in many cases are far more serious than bodily pain; namely, mental anguish due to the patient's constant realization of a defect which in turn causes the development of an *inferiority complex*, resulting in an attempt of the individual to withdraw from society. Though the world may seem at times too full of humanity—and especially the wrong kind of it—still we must be thankful for our fellowmen, for we cannot live without them. Even the lonely miner in the far-off mountains finds himself affected with hallucinations because he is not buoyed up by the necessary human stimuli. He knows that as the danger signal warning him to hasten back to civilization where human contact restores his equilibrium. Hence, the type of introvert who has withdrawn from society because of a deformity will doubtless never take his normal part in life until his whole outlook is

Case I Figure 1

Case I Figure 2

changed—by correction of the impaired portion or function, thus removing the focus of his inferiority. Likewise, in this machine age in which the number of men and women employed in gainful occupation is decreasing so rapidly, and in which competition is so keenly acute, persons afflicted with physical disfigurements are much less likely to secure employment than are their physically normal competitors. Therefore, our problem is immediately placed on an economic basis. During this present depression the economic importance of a person's appearance has been especially stressed, and we are constantly besieged by patients who want all sorts of physical defects repaired, the reason in all cases being that they "cannot obtain work because of their appearance." Consequently, many dependent persons are made self-respecting and self-supporting members of society by the removal of physical and resulting mental handicaps.

Again, plastic work has its legal aspects, for reparative surgery has been found invaluable in reducing disfigurements resulting from wounds and from automobile and industrial accidents. In one case the sentence of an offender was shortened several years by a nice repair of the loss of his victim's nose, which was severed in a fight in which knives were used. In cases of automobile injury we can so repair the defect that very little functional or disfiguring damage remains, thus relieving the insurance companies of damages for permanent disabilities. In compensation cases,

we can frequently repair the various deformities so that the patient can resume his former occupation. Therefore, it is readily seen that by restoring the patient's former state, we can remedy many difficulties that formerly involved much legal routine.

Case II Figure 1

Though the field for this type of work is a very broad one, and the indications manifold still at the present time there are limitations in plastic surgery which both the general practitioner and the surgeon should recognize. We are unable to transplant corneal tissue by means of which we might replace an opaque cornea with a clear one. We are limited as to the repair of big blood vessels and nerves, which makes it impossible to repair severed members successfully. At times we are hindered in accomplishing a perfect result by the great extent of the damage or by the inability to match skins. It is most important that the surgeon make clear to the patient, not only what result is to be expected, but also what obstacles might be encountered which might lengthen the process or possibly even interfere with the final outcome. Occasionally, a completed case which is quite pleasing to the surgeon may be absolutely distasteful to the patient, but in all fairness let me say that this situation is very rare, as most patients are more than appreciative.

Looking into the near future, we may safely wager that as the methods of asepsis become more absolute and their administrative technique

more accurate, we will be limited in our scope only by the cooperation of the patient and by our own perseverance over an extended period of time. And again, in conclusion, let me stress that plastic surgery has established its right for existence not only through its success in the repair of disorders of function, but also through its ability to rehabilitate those individuals who suffer solely from mental torment because of physical disfigurement without disturbance of function.

CASE REPORTS

Three cases of facial deformity from the plastic department of the New York Post-Graduate Hospital present distinct economic problems, and illustrate various methods of correction and repair.

Case II Figure 2

Case I A young woman who graduated from a Teachers' College and who was unable to secure steady employment because of a facial deformity. Figure 1 shows the condition on admission to the hospital. To correct this deformity it was deemed advisable not to attempt any bone manipulation because she had satisfactory mastication. An incision was made along the lower angle of the jaw on the right side, and the tissues over the depressed area were elevated. The defect was then filled in by the use of a dermo-fat-fascial graft taken from the left abdominal wall. The above graft was obtained by first shaving off the epithelial layers of skin and then cutting the shaved area to size, including fat and the super-

ficial fascia of the abdominal wall. This entire mass was then placed in the defect and the skin edges closed, using several silk sutures. A pressure bandage was then applied, and left for four days. The abdominal defect was closed by first undermining the cut edges and then sewing them together. The patient left the hospital two weeks after admission.

Case III. Figure 1.

Figure 2 shows the final result, and upon re-application she was given a permanent teaching appointment by the same school board which had previously refused her.

Case II. This presents a deficiency of the chin due to malocclusion. To remedy this appearance an incision was made internally at the buccal-gingival junction. The soft tissues of the chin were elevated from the jaw bone and, to give prominence to the chin, a rib cartilage graft was inserted between the bone and soft tissues. The edges of the mucous membrane were then carefully sutured, and a pressure bandage applied for a period of six days. The patient left the hospital two weeks after admission and returned at a later date for correction of her hump nose because this type of nose tends to exaggerate chin deficiencies. Figure 2 shows the final result. The patient secured desirable employment.

Case III. A man who had a portion of his lower lip removed for carcinoma in the skin clinic of the New York Post-Graduate Hospital. He

Case III. Figure 2.

was unable to carry on his regular work because of his appearance (Figure 1).

Figure 2 shows the method of repair. A tube pedicle graft was taken from the anterior fold

Case III. Figure 3.

of the neck and attached to the lip the grafted portion being nourished by the end attached to the neck. Figure 3 shows the finished operation

which was completed by severing the tube at both ends and discarding it. After complete repair he was able to resume his former occupation.

RECORDED AND RESIDENT DEATH RATES IN NEW YORK STATE

By J V DE PORTE, Ph D, ALBANY, N Y

Director Division of Vital Statistics New York State Department of Health

IV—INFANT MORTALITY, 1927-1930

ONE of the outstanding achievements in the field of public health has been the great reduction in infant mortality. A quarter of a century ago Sir George Newman, the eminent British sanitarian, deplored the fact that "although the general death rate is decreasing, the infant mortality is not declining." At that time the statement was true, not only for Great Britain but for most, if not all, of the civilized countries of the world.

In the course of the following years the situation changed radically. The rate of infant mortality has been moving almost uninterruptedly downward—faster than the total death rate. In the State of New York in 1915 (the earliest year when the registration of births was practically complete) the infant mortality was 99 per 1,000 live births, in 1930 it was 58. Thus, in the fifteen-year period the rate dropped 41 per cent, again, in 1915 infant deaths represented 16.4 per cent of the mortality at all ages, in 1930 the proportion was practically half of the earlier figure, 8.6 per cent. While it is true that the declining birth rate accounts for some of the decrease in the total number of infant deaths, even when the necessary correction is made for this factor, the last percentage is raised only to 9.6.

The causes leading to the death of an infant may be divided into two large classes: (1) antenatal and neonatal factors, operating before, during, and just after birth while the infant is still adjusting himself to an extra uterine existence, and (2) post natal factors, consisting to a greater extent of environmental influences. The first set of causes acts during the foetal state of the infant (fatalities taking the form of abortions, miscarriages, and stillbirths) and for several weeks after birth. The majority of deaths during the first month is due to congenital debility, congenital malformations, premature birth, and injuries at birth. Deaths at a later age, even those induced by prenatal causes, are to a large extent associated with environmental influences.

The progress made in the saving of young lives has been due primarily to the reduced total of deaths from gastrointestinal and respiratory diseases, to which fall victim mainly infants over one month old. The movement of the death rates

from causes operating during the first month of life has been less favorable. A considerable reduction was recorded in the mortality from congenital debility and premature birth. On the other hand, the death rate from congenital malformations remained practically stationary, while the rate from injuries at birth even increased.

It is, of course, impossible to postulate an irreducible minimum of infant deaths. The mere fact, however, that in certain countries infant mortality is now lower than in this country (New Zealand, to take a notable example, had a rate of only 34.5 in 1930) shows that our rate is still unnecessarily high.

Any effort to reduce infant mortality in a community must be based upon an accurate measure of that mortality. Infant mortality rates are expressed in terms of live births, thus, when we say that the rate of the State of New York in 1930 was 58 we mean that for every thousand infants who were born alive in the course of that year there were recorded 58 deaths of infants under one year of age. The recorded rates are subject to a varying degree of error because many births, to mothers who are residents of rural and smaller urban communities occur in the hospitals of neighboring cities. These births, as well as the deaths occurring among the newly born babies are recorded in those cities. Occasionally, local health departments in refining their infant mortality rates, deduct the deaths of infants whose mothers were non-residents of their communities, but do not consider the non resident births. Such a one sided correction is palpably wrong. In making a correction for residence it is clearly necessary to allocate not only the infant deaths but also the births.

Main Divisions of the State The recorded and resident infant mortality rates of the main divisions of the State in 1927-1930 are shown in Table I.

The allocation of births and of infant deaths according to residence of the mother increases slightly the New York City rate. There is no sustained change in the rates of urban and rural Upstate sections. In three of the four years the urban resident rates were higher than the recorded, while in 1930 the resident rate was slightly

cancer of the cervix offers fewer chances of a cure by proper irradiation.

On the other hand, cancer of the mouth and skin, are becoming preventable diseases. The modern woman is teaching men how to smoke with the least risk of cancer, because women keep their teeth clean and report to a dentist the moment they notice a sore spot. No one under the proper care of a dentist should develop cancer of the mouth. The same is true in regard to the skin. Women pay attention to any skin lesion or blemish and therefore come under the observation of the medical profession before cancer has developed. I have not observed a cancer of the skin over the nose the result of the chronic irritation of the never-slip vanity glass in the last five years. Either women or opticians, or both, are fully aware of this possibility.

We have no evidence as yet that cancer of the breast like cancer of the cervix or skin, or mucous membrane of the mouth can be made a preventable disease. We do not know the local conditions that precede a cancer of the breast.

We do know that if the lump just observed proves to be cancer when explored, the probability of a five-year cure, when the glands are not involved, varies from seventy to ninety-five per cent according to the type of cancer. If the glands are involved, the five-year cures fall to twenty-five per cent, when the base glands only are involved; to twenty per cent when the mid-glands show cancer cells, and to ten per cent when the apex glands, the highest are affected. These results are obtained only after the very best surgery. There is little evidence the pre- or post-operative irradiation increases the number of these permanent cures, although both x-rays and radium are our chief therapeutic agencies in the relief of pain from metastasis and in temporarily checking the rapid growth of cancer cells in some metastatic areas.

Our object, therefore, must be to increase the number of cancer lumps in the breast explored, recognized with the microscope and completely removed, before the glands are involved. In the first place, there is every evidence that if every lump in the breast observed in a woman over twenty years of age were removed within a few days after it has been felt, the chances are that a large number of precancerous areas would be eliminated from the breast, and, in this sense, cancer prevented. However, at the present time the chief hope of decreasing the number of deaths from cancer of the breast lies in giving the women the benefit of the radical operation before the glands are involved. This will increase the cures from an average of less than twenty to

an average of more than seventy. To accomplish this, more and more mothers must follow the recommendation of a semi-annual pelvic examination during which the breasts are properly inspected, palpated and transilluminated. More and more women, whether mothers or not, must learn and practice the rule of modern medicine—select your family physician while you are well, seek your first annual examination while you are well; and between these annual visits to your physician, report the moment there are any warning signs or symptoms in any part of your body. As a matter of fact, many people are doing this today. There is first, the prenatal clinic. Then, a large number of people see their dentist, oculists, dermatologists at proper intervals, and an increasing number are seeking annual examinations.

The Progressive Change for the Better Among the Correctly Informed Women Who Seek an Examination Immediately After the First Warning Sign or Symptom: By 1910 we were able to contrast the results of treatment between the first decade up to 1900 and the second decade up to 1910. At this time there had been no general educational program. The complete operation for cancer was well established, and the results in large clinics had been estimated. In the second decade, there was an increase in the per cent of five-year cures largely explained by the increase in the number of cases of cancer of the breast without involved glands. The two factors which influenced prognosis were the grade of malignancy of the breast cancer and the absence or extent of involvement of the glands. Early intervention had less influence on low grade cancer than on the more malignant types. But there is no question that the only factor over which we had control was the duration of the lump in the breast.

In the beginning, the early cases came from members of the families of the faculty and of outside physicians, and most especially marked were the patients of those practitioners of medicine who had the greatest confidence of their patients. It is unnecessary to go into details. Fortunately we had card indexes of the patients according to the doctors who had referred them to the clinic. In my first extensive studies, in 1910, which included every malignant tumor recorded in the laboratory of Johns Hopkins University, I was struck with the factors which brought patients early to the surgical clinic and with the factor of the grade of malignancy.

It was this evidence from this and other clinics that allowed Samuel Hopkins Adams to write his popular articles in lay journals. It was these observations that justified the

organization of the American Society for the Control of Cancer

There are four decades, and since 1910 there has been a gradual improvement along all lines. The number of women seeking advice because of breast symptoms has increased five times. With this, the incidence of cancer has fallen from more than eighty to less than ten. Inoperability has fallen from more than fifty to less than five per cent. Benign lesions subjected to operation have increased from less than twenty to more than fifty per cent. The five year cures have increased from less than ten to more than fifty. Benign breast conditions for which operations are not necessary have increased from less than one to more than eighty.

This progressive change varies in different parts of this country. The more the medical profession performs its part in the continuous, systematic instruction of the public, the better are the figures.

The Increasing Difficulties of Clinical and Pathological Diagnosis Among Women Correctly Informed Who Seek an Immediate Examination. In the first place, we know that in this type of woman the chances are that there will be a definite lump which should be explored in less than twenty per cent of the cases only. Therefore, in eighty per cent it must be decided by inspection, palpation and transillumination of both breasts, by a careful study of the clinical history whether operation is indicated.

Today the majority of women who report for an examination the moment they observe any sign or symptom suggesting trouble with the breast present on examination no indications of cancer or even for any operation. In less than 20 per cent the breast presents a definite lump and in most of these cases there are no signs of cancer. Therefore, today the first diagnostic dilemma is to find a lump which justifies exploration. The second diagnostic difficulty is to differentiate when that lump is removed by gross and microscopic study the benign from the malignant.

For example, quite recently a woman of thirty three complained of a lump in her breast. It was situated in the upper hemisphere where it could not be transilluminated. The lump was not larger than a twenty-five cent piece. Three of us in the clinic carefully studied the case by careful palpation. We all concluded that it was a benign cyst buried in breast tissue. At the exploration it was a small scirrhous cancer buried in edematous breast tissue. Less than two years ago, there were observed two similar cases. The one we diagnosed cyst proved to be cancer, the second one, in which we favored the diagnosis of cancer proved to be a benign cyst. The same is

true of very large tumors of the breast. Only exploration with frozen sections will distinguish between the sarcoma and the benign intracanalicular fibroadenoma, and the large aberrant fibroadenoma. There is no difficulty in feeling a definite lump in the breast. If this lump is the size of a twenty five cent piece or larger and transilluminates clear, operation is not indicated. If there are one or more definite lumps and all transilluminate clear, the removal of even a single one is not necessary. The examiner, however, must have considerable experience with transillumination before he is justified in depending upon it. In small single, definite lumps it is dangerous to depend upon clear transillumination to exclude a solid tumor which may be malignant, for example, a colloid cancer.

In the majority of instances among the correctly informed women today, there is no definite tumor. A single indefinite tumor in one breast justifies exploration. A single indefinite tumor which the patient has picked out and the examiner can pick out in a lumpy breast or in a shotty breast, justifies exploration. When there are two or more indefinite tumors in one or both breasts, whether the breast be normal, lumpy or shotty, exploration is less urgent and in the hands of experienced examiners can be left alone without danger.

On palpation, one should become familiar with the various types of breasts which may be described as normal, senile, lumpy, shotty, the breast at puberty, the breast in pregnancy, the breast during lactation, the breast after lactation, the fatty breast large or small, the breast with excessive parenchyma with and without the history of lactation and palpating differently from the normal, lumpy or shotty breast.

There is no question that today every general practitioner and specialist interested in breast lesions are given more opportunities to palpate breasts in which there is no definite tumor. There is no question that cancer and distinctly benign tumors like the encapsulated adenoma and the cyst with intracystic papilloma occur in normal breasts. The chief factors in lumpy and shotty breasts are chronic cystic mastitis, and the mastitis of lactation without abscess. These conditions tend to ultimately disappear. When women waited after feeling a lump for months or years and entered the clinic with a definite lump, there was no difficulty whatever to distinguish this lump on palpation. Today, the educated woman comes to the examination the moment she feels a lump, and often she will feel an indefinite lump as readily as a definite one. In the majority of cases this lump which the woman thinks she can feel, with and without tender-

ness, is only part of a lumpy or shotty breast. There is no question that cancer in the beginning may be an indefinite lump and for some weeks or months the lump may remain indefinite. The larger the breast and the deeper the seat of the lump, the longer the period during which it remains indefinite. There is no reason for further discussion—the fact is today, among enlightened and courageous women, there is to be more and more difficulty in picking out the single lump which is indefinite and situated in a shotty, lumpy breast, and subject it to exploration for frozen section. The actual per cent of cancer in such instances is not large, but practically all these cases, if explored at once, should be cured. Therefore, if there is any doubt about the nature of the indefinite lump, it should be explored, studied, in the gross and in the frozen section, and, of course, if it is malignant, the complete operation for cancer must be performed.

What to Do If the Surgeon, With the Aid of His Pathologist, Can Not Decide from the Fresh Gross Appearance and an Immediate Frozen Section the Exact Nature of the Explored Tumor in the Breast: My associates and myself have given this problem more than usual attention in the past two years. Our conclusion is based upon the breast tumors referred to the laboratory by outside surgeons and pathologists and from the diagnoses of pathologists and surgeons from all over the country who have attended the microscopic demonstrations which now have taken place in the laboratory for two years three times a year.

No surgeon without pathological knowledge and without the assistance of a trained pathologist should explore these indefinite breast tumors, because the only safe procedure would be the complete operation for cancer in every instance. On the other hand, when the surgeon and pathologist have the training of the average, and are unable to recognize cancer, it is safe to excise the area with a margin of healthy breast tissue, close the wound and submit the tissue to one or more consultant pathologists. In the great majority of the cases the lesion will prove to be benign and, if malignant, it will belong to the rare type of low-grade duct cancer or colloid cancer in which the danger of a few days' delay between the excision of the tumor and the complete operation will not lower the per cent of five-year or permanent cures. This conclusion is almost a reversal of that usually reached fifty years, and even five years ago.

We are preparing to submit the detailed evidence in favor of this statement.

What Special Training and Assistance Should the Surgeon Have Who Takes the Responsibility

for Exploring a Breast Tumor?: In the first place, the great advantages of the surgeon who is a good gross pathologist as well as a clinical diagnostician, are less valuable today than of the surgeon who is trained in microscopic pathology. It is true that the opportunity for a surgeon to become a microscopic pathologist is more limited than to become a gross pathologist, and, in addition, it was easier to learn naked-eye diagnosis in the late stages of the disease than microscopic differentiation in the earliest. However, today, if a surgeon is not a microscopic diagnostician, he must have with him a trained microscopic pathologist.

Whether the surgeon is microscopic diagnostician or not, the best results for the cure of cancer of the breast are obtained not only by the best surgery, but by a special training in the accepted technique for the complete operation for cancer of the breast.

The operator must improve his technique in the physical examination of the breast and should follow a well-thought-out method of inspection, palpation and transillumination. The pathologist cannot do this for him. Therefore, the training of the surgeon should be in the decision whether there is a definite lump which must be explored, and in the operative removal of the lump, and in the complete operation for cancer of the breast. In addition he should associate with himself a pathologist properly trained in the microscopic diagnosis of tissue; removed in the operating room, by the rapid frozen section method.

The disease in the breast which is giving the most trouble to differentiate it clinically and microscopically is chronic cystic mastitis. When the symptoms observed by the woman are of but a few days' duration, the most common condition of the breast is chronic cystic mastitis. When women delay for months or years, the most common condition of the breast becomes cancer, and, as a rule, hopeless cancer, although it may still be operable.

What Every Physician in General Practice Should Know About the Breast: Unfortunately, the majority of medical students, even today, are given little opportunity to palpate breasts in women, and many receive no special instruction, and for this reason the breasts in the routine examination of women in the dispensary and in the hospital wards, is largely neglected.

Both medical students and the general practitioner should follow a definite plan in the examination of the breasts of all women who come under their observation for some form of physical examination. It should be as precise and thorough as the now recognized phys-

ical examination of the chest the pelvic examination, the urological examination, the examination of the eye. When all women seek annual or semiannual examinations and report to their family physician the moment they experience breast symptoms, the general practitioner will have an increasing opportunity to improve his diagnostic abilities as well as to systematize his methods.

Methods of Examining the Breasts In the first place, the examiner should be ignorant of which breast the patient thinks is involved and what symptoms she has experienced. That is, the examination should be identical whether the breasts are being studied in a routine physical examination, or because the patient seeks examination for definite symptoms.

The preparation should be the same as for a physical examination of the chest—the patient should strip to the waist. The individual should sit sideways on the examination table, properly covered to protect her from cold until the examination begins. The table should be so placed that the examiner can walk around it. First inspect the exposed upper trunk, arms, neck, head and face. Look for skin defects, thyroid enlargement, pulsation in the neck. Look at both breasts, with the arms of the patient down. Note specially the nipples and areolæ and the skin over the breast. Look for any irritation and keratosis of the nipple, for retraction and any sign of a discharge. Note the size and symmetry of the breast, asymmetry, bulging nodule, dimpled skin, redness or any discoloration. Have the patient slowly lift the arms in the air a number of times. Observe whether there is any difference between the movements of the breasts or nipples, especially retraction or dimpling of the skin. When the arms are raised observe the axilla. Don't touch the breast until this inspection is complete. Then let the arms fall to the sides, darken the room and transilluminate. Place the light first behind the nipple zone. Learn to distinguish the dark lines of branching veins. As a rule, if there is a single, definite tumor which is solid, or if there is a cyst filled with blood or grumous material, this area will be picked out as quickly with the cold light as with the finger. Small cysts with papilloma in the nipple zone which may not be palpable are often brought out by transillumination. Tumors in the middle of the upper hemisphere as a rule cannot be reached by the light. Next palpate both breasts with one hand to each breast and then one breast with both hands. Palpate gently. Do not pick up and pinch the breast tissue. Leave the nipple zone temporarily alone. If you palpate a tumor in the sitting position and it is in a situation in which you can place the lump

beneath it, try the transillumination test again and again. Now the patient should lie down and hold the arms over the head. Inspect again, palpate again, palpate from both sides and when striding at the head of the examination table. Press gently on each breast to see if you can express material from the nipple. Palpate the areola for dilated ducts beneath the nipple. When you feel a worm-like mass or a nodule near the nipple, press on it gently and see if anything is expressed from the nipple. While you are palpating the region of the nipple, the apparently retracted nipple may protrude, or you may produce intermittent retraction of the nipple. Ultimately pull each nipple forward to detect any fixation, no matter how slight. When a definite lump is found, study it most carefully, especially for dimpling or fixation of the skin. When the patient is lying down, palpate for a definite edge of the breast. If there is a definite edge, see if the breast when picked up is saucer shaped. No matter how definite a single lump may be, never neglect the complete study of both breasts. The less definite the findings, the more thorough the study, and as a rule this should be repeated at least once again in a few days or a week. This thorough examination of both breasts decides whether an operation is to be performed or not.

Conclusions I have covered the more important points in a much more emphatic and decisive way than has been possible in previous communications. I have tried not to repeat what has been well described in my former contributions to the literature, because every one who reads this may read the others.

The essential features, then, in the attempt to reduce the deaths from cancer of the breast in women are: The recommendation, through education, of annual and semiannual examinations by a competent physician selected while well, the education of the general practitioner on the proper physical examination of the breast so that he may select those patients who should be referred to a consultant with the least risk to those whom they diagnose themselves as belonging to a group of benign conditions for which operation is not necessary, the training of the surgeon to meet the new demands in the search for the lump that should be explored, and the training of that surgeon to maintain the technique of the complete operation for cancer successfully established more than thirty years ago, the training of the pathologist in the more certain differentiation between the benign and malignant breast tumors in the fresh frozen section made in the operating room.

I will not take up the equally difficult management of the more advanced or hopeless

cancer of the breast, of the different types of local and regional recurrences and remote metastasis; the decision as to pre- and post-operative irradiation; the choice between x-rays and radium; the attempt to make the dying patient more comfortable; the psychic control of the hopeless case, even when the patient is not suffering from pain; the danger of giving prognosis, and a large number of detailed questions which are unfortunately far too common today, because many women still delay when warned.

Brief summary of essential statements in this paper:

Protection Against Cancer of the Breast: Thousands of women who have read the correct information in the daily press or who have learned it from their family physician, or have acquired the modern habit of annual examinations, have shown that the greatest risk a woman runs today if her lump proves to be cancer, is about twenty-five per cent, while the ignorant woman who delays largely because of her ignorance and not of fear, has less than ten per cent chance of a cure.

Women need no instructions in what the warnings are. They will recognize them in time. But every woman needs special instruction how to act when warned. Recent figures show that when a woman seeks an examination the moment she observes anything unusual in one or both breasts, the chances are that eighty-five per cent of the warnings will be of such a character and the examination of such a decided finding, that no operation or irradiation with X-rays or radium is necessary. In about fifteen per cent of the cases a lump of such distinct character will be discovered by the finger of the physician or the transilluminating light, that the lump must be removed, and the lump only. The lump is immediately subjected to microscopic study. In less than one-half the cases, cancer or suspicion of malignancy will be discovered by the microscope, and the complete operation with removal of the breast must follow. In more than one-half the cases only the lump will have to be removed and the breast saved. Therefore the woman who seeks an examination at once runs the risk of cancer in less than ten per cent of the cases and increases her chances of a cure from less than ten to more than seventy per cent. Those who delay increase the incidence of malignancy and decrease the chances of a cure.

Without doubt annual examinations of all women and semi-annual pelvic examinations of mothers during which the breast will be carefully surveyed, should increase the protection of

women from death by cancer of the breast. As yet we do not know how to prevent the development of cancer in a woman's breast, but we do know how to teach and influence her to have the cancerous lump discovered and properly removed early, so that the chances of a permanent cure are best.

TO THE PEOPLE

The Board of Directors of the American Society for the Control of Cancer, after careful consideration, issued the following statement, March 7, 1931. This has already appeared in the New York Times and the New York Herald Tribune for Sunday, March 8, 1931.

In the opinion of the Board the only effective treatments for cancer today are surgery or irradiation with X-rays or radium. It further desires to emphasize the point that the best palliative or permanent results are to be obtained when the treatments are applied as soon as possible after the first warning symptoms.

"The Board also wishes to make this statement to the public: If people wish the greatest possible protection against cancer and other disease they should, while they are well, select a family physician if they can afford it, or a clinic while they are well and should ask not only for an examination but for advice on the rules of health and on the earliest symptoms of disease."

TO MOTHERS

The almost unanimous opinion of 900 obstetricians, Fellows of the American College of Surgeons and many other Physicians and Fellows of the College, is that mothers' best protection against cancer of the cervix of the womb depends upon the repair of all injuries and irritations following the birth of a child, and semi-annual pelvic examinations thereafter.

Every woman should know that anything observed unusual in the monthly period; the appearance of a discharge, with or without blood, between periods; and the reappearance of the menses or any discharge after the menopause (change of life), are warning symptoms which demand an immediate proper examination by a competent physician.

Consult your family physician about this statement.

Do it now, regardless of any previous examination or conversation.

This statement is based upon the recent research work of the Amanda Sims Memorial Fund for the Protection of Women from Cancer by Correct Information.

CERVICAL CANCER. ITS 1926-1929 INCIDENCE IN FIVE N. Y. STATE CITIES. ITS PREVENTION. ITS FUTURE*

By GLENN A. WOOD, M.D., SYRACUSE, N. Y.

From the Department of Obstetrics, Syracuse General Hospital

IT has been determined¹ that in the United States over 13,000 women die annually from cancer of the female genital organs. 72% of this number, based on a future observation in this paper, have a cancer of the cervix. If every year 72% of a city such as Fulton, N. Y., or Little Falls, N. Y. or Tonawanda, N. Y. or any other city of about 13,000 population were to be suddenly wiped out of existence, I am sure governmental and individual attention would go to the very limit of investigation to determine the cause and correction of such a catastrophe. Cancer of the cervix takes this yearly toll, yet, it has not received the limit of investigation probably because of its widespread distribution and, therefore, low mortality rate in each individual area.

From our local Registrar of Vital Statistics, I have secured some data concerning Syracuse on the incidence of deaths from cancer of the female genital tract, or, as it is at present classified in the International List of Causes of Death, and hereafter referred to, as Code No. 46

I have personally interviewed a considerable number of the doctors who signed the death certificates to determine what percentage of deaths listed as cancer of the uterus should have been listed as cancer of the cervix, the primary site of the disease having been in the cervix. In this investigation I have found that 84% or 94 of those listed as cancer of the uterus should have been listed as cancer of the cervix; 9% or 10 were primarily cancer of the fundus or body and 7% or 8 were seen so late in the disease that a determination of the primary site in the uterus was impossible. It is entirely probable that some of these undetermined cases might have been primarily in the cervix.

The 12 deaths among unmarried women reminds us that Code No 46 is not entirely confined to women who have had injuries to the cervix during childbirth. With one exception, all of this unmarried group were over 50 years in age. A further analysis of the Code No 46 deaths among these 12 unmarried women shows that 1

TABLE A

DEATHS IN SYRACUSE FROM CODE NO. 46. (1926 TO 1929, INCLUSIVE)

Listed as to yearly totals, anatomic location, number from out of City and number that were single

	Total Cases	Ca of Cervix	Ca of Uterus	Ca of Vulva or Vagina	Ca of Ovary	From out of City	Single
1926	35	6	23	1	5	6	3
1927	42	9	30	0	3	5	5
1928	39	10	25	1	3	5	1
1929	45	5	34	2	4	7	3
TOTALS . . .	161	30	112	4	15	21	12

84% of Ca of Uterus is primarily Ca of Cervix 84% of 112 is 94
9% of Ca of Uterus is primarily Ca of Fundus 9% of 112 is 10
7% of Ca of Uterus is primarily undeterminable 7% of 112 is 8

Adding 94 to 30 (listed Ca of Cervix deaths) gives 124 or number of deaths in Syracuse from Ca of Cervix for years 1926 to 1929, inclusive..

. 124 is 77% of 161, the total Code No 16 deaths for 4 years

In Table A you will note that by far the greater number of deaths from Code No. 46 occur under the subdivision, Cancer of the Uterus. Cancer of the Uterus, as such, is an acceptable term to the Bureau of the Census for classification of deaths. This term, however, includes deaths not only from cancer of the fundus or body of the uterus but, as well, many more deaths from cancer of the cervix. Concerning the 112 deaths listed under cancer of the uterus, I

had a cancer primarily in the ovary, 2 were seen so late in the disease that it was impossible to determine the primary site of the disease in the uterus, 6 were primarily in the fundus or body of the uterus and 3 were primarily in the cervix. Among these unmarried women, cancer of the body or fundus of the uterus was two times more frequent than cancer of the cervix.

Later in this paper I will quote a noted gynecologist who believes that "the parous woman whose child-bed injuries have been wisely and skillfully repaired has at least an even chance

* Presented at the October 6, 1931, Meeting of the Onondaga County Medical Society at Syracuse, N. Y.

with her nulliparous sister of avoiding the later development of a cervical cancer." If the incidence of cancer of the cervix in the married group could have been reduced to approximate the incidence found in the unmarried group, we would have had nearly a 70% reduction in Code No. 46 for the four years '26-'29 inclusive.

No. 46 not only in Syracuse but also in four other New York State cities, namely, Buffalo, Rochester, Albany and Yonkers. In the preparation of these tables I am grateful to J. V. DePorte, Director, Division of N. Y. State Vital Statistics for his assistance in supplying the facts from which the tables are compiled.

TABLE B
INCIDENCE OF CODE NO. 46 IN SYRACUSE FOR 5 YEARS (1926 TO 1930) BY MONTHS

	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Totals
1926..	2	2	3	2	1	3	2	5	5	4	5	1	35
1927..	5	7	2	6	2	3	2	4	4	4	2	1	42
1928..	5	1	3	1	7	3	6	1	4	4	0	4	39
1929..	3	3	3	8	1	3	0	6	7	3	3	5	45
1930..	1	6	3	5	3	2	5	5	2	4	4	7	47
Totals	16	19	14	22	14	14	15	21	22	19	14	18	

Table B shows no particular month in which deaths from Code No. 46 seem to be more frequent.

This table makes the only reference in this paper to the number of deaths for 1930 from Code No. 46. The total number of deaths for 1930, 47, when compared with the other years shows that, except for the year 1928, there has been a steady rise in the number of deaths from Code No. 46 for the past five years. A fact not demonstrated on this table is, that in Syracuse for the first nine months of 1931 there have been 42 deaths from Code No. 46. 1931 bids to outnumber former years in deaths from this disease.

Table D shows Code No. 46 is common to these five cities.

As in Table A, by far the greater number of deaths are listed under cancer of the uterus.

I have previously called to your attention the fact that a large percentage of cancer of uterus deaths should more properly have been listed under cancer of the cervix. Although I have disregarded the probability in subsequent table compilations, it seems likely that at least some of the cases listed as cancer of the vagina and vulva, broad ligaments, abdomen, uterus and ovary, and uterus and vagina had the primary site of the disease in the cervix and should have, therefore,

TABLE C
INCIDENCE OF CODE NO. 46 IN SYRACUSE FOR 4 YEARS (1926 TO 1929) BY AGE GROUPS

	20 to 25	25 to 30	30 to 35	35 to 40	40 to 45	45 to 50	50 to 55	55 to 60	60 to 65	65 to 70	70 to 75	75 to 80	80 to 85	85 to 90
1926	1	1	2	7	6	5	7	2	3	1
1927	1	..	2	2	3	10	5	9	4	2	2	1	1
1928....	..	1	1	2	5	1	9	5	8	3	2	2

TOTALS..	1	2	2	5	12	14	32	20	38	10	15	7	2	1

Table C shows that the greater number of women died from Code No. 46 during these four years after passing the 40th year.

A discussion of the age incidence of cancer will be later made under Table H.

As a basis of comparison, I have prepared the following tables showing the incidence of Code

been listed under the title, cancer of the cervix.

Note the relatively low incidence of Code No. 46 in Yonkers and the relatively high incidence in Albany.

In Table E-1 you will note that Code No. 46 caused in these New York State cities from 10.8% to 17.8% (average 14.5%) of all the male and fe-

TABLE E-1
RECORDED DEATHS AND DEATH RATES PER 100,000 POPULATION FROM CANCER (ALL FORMS), ALSO, CODE NO. 46 PERCENTAGE OF THE TOTAL CANCER DEATHS

	1926			1927			1928			1929		
	Total Cancer Deaths	Rate	Code No. 46 %	Deaths	Rate	%	Deaths	Rate	%	Deaths	Rate	%
Buffalo	669	123.4	14.5	697	127.2	12.8	671	121.2	13.4	715	127.8	12.8
Rochester	396	124.0	13.1	410	126.9	17.3	461	141.0	16.0	432	130.6	17.8
Syracuse	222	116.8	15.6	246	125.1	17.1	290	145.6	13.4	282	139.8	15.9
Albany	204	171.3	16.1	219	183.2	13.6	218	181.1	12.3	192	158.4	15.1
Yonkers	101	86.8	10.8	100	84.2	14.0	117	96.4	14.5	123	99.4	13.8

male cancer deaths. In Syracuse for these four years ('26-'29 inclusive) Code No. 46 caused an average of 26% of all female cancer deaths. This fact is not demonstrated in this table.

Table E-2 shows that when the death rates from all forms of cancer are corrected for residence, the rates for Yonkers increase while the rates for Albany and the other four cities decrease. Note, however, that Albany has the highest relative cancer rate and Yonkers the lowest.

In the preparation of Table E-3 it was neces-

sary to assume for the four other New York State cities the Syracuse ratio of 84% of cancer of uterus deaths being cancer of the cervix. We find that there was in the five New York State cities, during 1926-1929 inclusive, a total of 721 cancer of the cervix deaths, which is 72% of the total Code No. 46 deaths.

In Table F there is no ratio between the birth rate and Code No. 46 death rate for these four years. For example, Rochester and Yonkers are the same regarding birth rate, yet Rochester is

	1929	123,802	17.7 3rd	13.8 5th	10.5 5th

considerably higher than Yonkers regarding the Code No. 46 rate. Buffalo is highest in birth rate while fourth in Code No. 46 rate. The majority of deaths from Code No. 46 occur years after the child-bearing age. Possibly the birth rate of twenty-five years ago might bear some ratio to the present Code No. 46 rate. The cancer of the cervix rate, based on the 84% Syracuse rate before mentioned, follows closely the Code No. 46 rate.

I have never heard nor read that native white were more susceptible than foreign born white to cancer in general or cancer of the cervix in particular.

It is my hope that the presentation of this table will in no way lessen the point that I especially desire to make, namely, that cancer of the cervix is common to Syracuse and other New York State cities. What is true of New York State is also probably true for the rest of the country and,

TABLE G

+Less than .1%.

Table G is presented for consideration because of the observation that the ratio of Code No. 46 deaths rather closely parallels the percentage of native white and foreign born white in these five cities.

You will note that Albany has the highest percentage of native white and the lowest percentage of foreign born white. This city, as before mentioned, has the highest Code No. 46 death rate. Buffalo, which is fourth in the Code No. 46 rate is also fourth in the percentage of native white population and third in the foreign born white population. Yonkers, which is lowest among these five cities in Code No. 46 deaths, is also lowest in native white and highest in foreign born white population.

for that matter, the world, for humanity is the same everywhere.

I submit this observation of the U. S. census of 1920 regarding these five N. Y. State cities to stimulate a more comprehensive observation regarding this interesting phase of the cancer problem.

Table H attempts to explain why Yonkers is lowest and Albany highest in Code No. 46 deaths.

This table parallels exactly the cancer of the cervix rate and closely parallels the Code No. 46 rate as shown in Table F, in that the order of cities having the highest and lowest rate of cancer of the cervix deaths also have the highest and lowest percentage of population under 45 years.

Yonkers with 80.4% of its population under 45

years should have a smaller cancer death rate than Albany with 73.5% under 45 years.

With a disease so universal, it is gratifying to read of authors expressing the belief that cancer of the cervix is largely a preventable disease. Some writers on this subject stress the recognition and correction of cervical lesions soon after their formation. As the majority of cervical lesions result from child-birth, it follows, that all who do obstetrics should inspect the cervix within a short period following the confinement and then correct the pathology that may be found.

to be satisfactory. A proper use of some of the above procedures will many times remove the necessity for a cutting operation.

It is my opinion that everyone who practices obstetrics should have some means for correction of the cervical pathology observable in the early secondary period of repair. The several methods above enumerated are all excellent procedures. Each have their particular advocates but each try to accomplish the same end result. It is not so important as to what method to employ as it is to select some method.

TABLE H
PERCENTAGE OF POPULATION BY AGE. UNITED STATES CENSUS OF 1920

75 Years and Over.....	1.0	1.3	1.4	1.7	1.0

In 1929, in New York State (exclusive of New York City) 73.3 per cent of the deaths from cancer were of persons 55 years of age or more, and 89.7 per cent of persons 45 or more.

Dr. Graves states² that "90 to 98% of cervical cancer has its origin in neglected obstetric lesions."

Dr. Dickinson states³ "It seems to me that no more important piece of work in the prevention of cancer of the cervix can be done than to drive home to every man who delivers a patient that it is his duty to see that the cervix is left healed after a delivery."

There are three periods, following their formation, when cervical lesions may be corrected. The first of these is immediately after their formation by the, so called, primary cervical repair. In a previous paper⁴, I described this technique and gave you my experiences as to the results obtained. I am still using this method of repair and the end results have been most pleasing.

The second period of repair is on the ninth or tenth day postpartum with the intermediate repair as described by Dr. Coffey⁵ and others.

The third period of repair may be divided into two parts, the early and late secondary periods of repair. The early secondary repairs of the cervix would include repairs up to the eighth week postpartum. The means of repair in this period would include the use of the electric cautery, the use of the high frequency current by conization or by the endotherm knife, the use of heat as by diathermy, the use of silver nitrate, mercuriochrome, etc. Here, also, I would include the use of surgery with removal of the diseased endocervix if some of the above measures were not found

The late secondary repairs cover all repairs of the cervix after the eighth week postpartum. All the types of repair of the cervix mentioned under early secondary repair would apply to this period. At this time the actual cutting operations such as the Sturmdorf and the Schroder etc. may be more necessary. Some find a use for radium in this late secondary period.

During the immediate, intermediate and secondary periods of repair the aim has been to restore the damaged cervix to normal and, therefore, eliminate a source of chronic irritation with its sequellae. In this connection, it is instructive to note the often quoted statistics of Dr. Graves.⁶ In his study of 538 cases of cervical cancer he found only "12 patients or 2% had had a previous repair of the cervix. In 2 of these 12 cases a re-examination of the specimens of cervical tissue revealed that a cancer had existed at the time of the repair operation and had been overlooked by the pathologist. In another case there was no pathologic record but the symptoms of cancer ensued so soon after the repair operation to make it probable that the disease existed at that time. If, therefore, these 3 cases of already existing cancer are excluded there are left only nine which later developed cancer after cervical repair, and, in most of these, early pathologic records were lacking. On the other hand, out of nearly 5000 cases of cervical repair there were records of only 4 that had developed a cancer later and in 2 of these the disease was conceivably encouraged by

unskillful plastic operations which had resulted in extreme obstructing stenosis of the upper vagina and cervix, conditions which probably play an important part in the production of genital cancer."

These statistics of Dr. Graves are "of value in supporting the belief generally held, and now rationalized by science, that timely reparative operations insure an effective, though not a perfect, prophylaxis against cancer." It is Dr. Graves' personal belief "that the parous woman whose child-bed injuries have wisely and skillfully repaired has at least an even chance with her nulliparous sister of avoiding the later development of a cervical cancer."

Pemberton and Smith⁷ state "In a series of 3814 trachelorrhaphies, 740 amputations and 1408 cauterizations of the cervix (total of 5962 cases), only 5 are known to have developed cervical cancer, and these were in the trachelorrhaphy group. That only 12 out of 669 patients with carcinoma of the cervix had had trachelorrhaphy and that none had had cauterization or amputation also suggests the prophylactic value of careful cervical treatment."

What is the future of cancer of the cervix? The future is a physician-patient responsibility, with much emphasis on the physician. The physician must insist on the sixth week check up examination. This examination must be thorough, including the use of the speculum. In this connection I have made an interesting investigation. I have asked 100 women, either friends or patients, who have borne children whether or not they were requested by the doctor in attendance at their last confinement to return for a six weeks check up examination. Thirteen per cent had been so requested, although only ten per cent had actually gone for the examination while eighty-seven per cent had not been asked by the physician to return for this important examination. Ladies and Gentlemen this is one, self evident answer as to what is the future of cancer of the cervix.

When pathology is found it must be early corrected by any of the several methods above enumerated. If the physician is incapable of doing this, he should be duty bound to refer this patient to one who can. The obstetrician's responsibility should not cease until the cervix is returned to normal. The yearly health examination offers an excellent opportunity for the examiner to ascertain the condition of the cervix in those women who have borne children. Here, again, the responsibility rests largely with the physician.

If the death rate from cancer of the cervix is ever lessened, organizations, be they medical or lay, must devote more of their energies and finances toward the education of physicians who are doing the obstetrics of today. This education must

emphasize the importance of early diagnosis and treatment of cervical cancer's progenitor lesions. All propagandas for early recognition and treatment of cervical cancer are, truly, important projects. Usually omitted in the propaganda is any reference that the recognition and correction of the progenitor lesions, soon after their formation at childbirth, should be the first aim of effort in the elimination of cervical cancer.

Prophylaxis of cancer should have an equal emphasis with diagnosis and treatment, yet, so many times in the literature is this most important phase of cancer elimination relegated to the background or absolutely ignored.

The similarity of the present organized fight against tuberculosis and the possibilities with such an organized effort against cancer are noteworthy.

I believe there already exists in State, County and Municipal governments an organization which is as fully capable of assuming the responsibility for the fight against cancer as it was when it assumed the liability for the fight against tuberculosis.

State, County and Municipal governments have a Department of Health with the broad function of prevention and cure of such conditions that are detrimental to the health of its citizens. To the Department of Health, therefore, should this fight for cancer reduction naturally fall.

Such a plan would offer the following advantages: 1 It would centralize responsibility. 2 It would put into operation an organization already working on health problems. 3 It would make use of an organization financially responsible to start, continue and slowly enlarge the program for cancer reduction. 4 It would carry the fight to the smallest hamlet as well as the largest of urban centers.

New York State is already at the business of trying to reduce the incidence of cancer. Its diagnostic and therapeutic facilities at Buffalo are models of competency. Even if there were several more State Cancer Institutes there would still be need for the advocated centralized Bureau of Cancer to maintain the constant educational program for both the laity and the profession. It is only by continuous educational propaganda that results can be obtained.

In conclusion, I would call to your attention the slogan of the New York State Department of Health "Public Health Is Purchasable Within Natural Limitations Any Community Can Determine Its Own Death Rate." The death rate from cervical cancer can be reduced. We should not be contented with the increasing incidence of this disease. Rather, we as individuals, organizations and communities should recognize the truth in the slogan and by a more organized effort strive to lessen the death rate of this formidable disease.

VINCENT'S OTITIS MEDIA IN INFANCY

By I. NEWTON KUGELMASS, M.D., NEW YORK, N. Y.

From the Department of Pediatrics, the Fifth Avenue Hospital, New York.

EARLY diagnosis, particularly if followed by local and systemic treatment of Vincent's infection in the upper respiratory tract of children, is preventive of irreparable destruction of bodily tissues. Dental literature abounds with statements indicating lack of susceptibility of children to Vincent's infection and yet over three hundred cases have been treated in our dental service in cooperation with the department in the last two years. Great emphasis has been placed upon local therapy in spite of the systemic manifestations that have been conclusively demonstrated by Tenney in the large series of cases observed in this hospital.

The present case is illustrative of the sequence of events which proceeded from a relatively innocent throat infection thoroughly neglected. The rarity of reported chronic otitis media due to Vincent's infection is undoubtedly due to the universal failure of examining bacteriologically ear disturbances. To be sure cases of noma of the ear, now practically extinct, are the results of fusiform bacilli associated with spirochetes emanating from a previously neglected otitis media but there are a series of stages between the initial upper respiratory infection and a fatal noma of the ear for Vincent's infection to be recognized and treated enough to prevent exodus.

Garcia A., a Porto Rican female infant of 19 months was admitted to the service the first of the year with a temperature of 104° which alarmed the parents after a week of her neglect with a marked upper respiratory infection. The child was malnourished and showed skeletal manifestations of old rickets. She was toxic, the breath fetid, the pharynx markedly injected, the ear drums were bulging, the nose discharging muco-pus and the neck showed considerable glandular enlargement. The gums were bleeding and studded with patches of grayish membrane which covered both tonsils. The chest revealed coarse rales throughout; the heart was normal; the abdomen was distended; the spleen was 2 c.c. below the costal margin; the liver was not enlarged. Nose and throat cultures were taken and diphtheria antitoxin administered by the resident physician.

The mouth condition was typical of Vincent's rather than of diphtheria as was confirmed by laboratory findings of fusiform bacilli and spirochetes. The child was treated

locally with 10% chromic acid and irrigated every four hours with sodium perborate. But the spontaneous rupture of both drums revealed a thin fetid discharge of the right ear characteristic of Vincent's infection. The first attempt at irrigation resulted in the return of the fluid through the nose and mouth due to large perforations involving the lower two-thirds of the drum, obviously an extension of infection through the Eustachian tubes through the naso-oro-pharynx. The early cultures from the ear showed fusiform bacilli and it was not until sometime that the spirilla were found. They live in symbiosis with the fusiform bacilli, increasing in concentration as the disease progresses. Pyogenic organisms which prepare the soil for the anorobes were, of course, also present. The ear organisms appeared identical with those taken from the various parts of the mouth and pharynx.

All attempts at local ear therapy with variously treated tampons have failed to yield improvement. The systemic manifestations revealed by the toxicity, the septic temperature, the vomiting, the anemia, diarrhea and pyuria were indications enough for systemic therapy. Neo-arsphenamin (15mg.% per kilo. of body weight) was injected once weekly as a supplementary procedure to all local attempts to clear the deep-seated Vincent's infection.

The child was given a transfusion of 160 c.c. of blood and was maintained on a high caloric base-forming concentrated dietary throughout her stay at the hospital. The Schick, Dick, Mantoux and Wassermann tests were negative. The white blood count was 14,000, polys 72, lymphocytes 24, hemoglobin 70 and red blood cells 4,000,000. The films of the accessory sinuses showed increased markings of both antra secondary to the Vincent's infection. A double simple mastoidectomy and adenoidectomy were performed by Dr. Hunt in order to save the child's hearing. The sinuses were treated with argyrol packs. In spite of all attempts to clear this persistent infection the child returned one-half year later with a chronic fetid discharge of the right ear which showed Vincent's organisms bacteriologically. The mastoid wounds were well healed, the tonsils were markedly enlarged and cryptic and were therefore removed to eliminate an obvious focus of infection that had persisted for some time.

THE GOVERNOR'S HEALTH COMMISSION

Public Health administration has been the subject of intensive study in New York State during the past two years, first by a special health commission appointed by Governor Franklin D. Roosevelt, and, secondly, by a committee of the Medical Society of the State of New York.

The Governor's Commission considered problems of public health from the point of view of

the office holder, not only in health departments but in other branches of governmental functions. The Commission recognized four general principles in the basic relation to the state of health:

1. Health deserves the consideration of governmental officials equally with education, transportation, taxation, police protection, and other governmental functions

2. The Commission proposes to extend the resources of the government in providing the means of medical care which individual patients and family doctors cannot supply,—as for example, a major operation on a crippled child and the long after-care and muscle training.

3. A responsibility for health lies with officials of local municipalities, as well as those of the State.

4. Scientific knowledge, administrative experience, and public sentiment have reached such a stage of development and evolution that a group of thoughtful men can devise a practical system of health administration suited to present conditions.

The personnel of the Governor's Health Commission consisted of men and women whose experience was along the lines of administration in distinction from the active practice of scientific medicine. This fact is of great importance in comprehending the true significance of the Commission's report. The suggestions of the Commission may be taken to be those which legislators and officeholders generally will be inclined to adopt.

The report of the Commission also had the great value of being a concrete expression of general principles whose interpretations have varied widely among different groups whom they effect. The report was like a preliminary sketch of a sanatorium, or the outline of a play which is subject to change as the plot develops.

After the report of the Governor's Health Commission had been published in the Spring of 1931, it was considered by a committee of the Medical Society of the State of New York which studied it from the point of view of the great body of physicians who are engaged in the active practice of medicine. They continued their investigations over a period of six months, and met in several sections of the State, and urged the representatives of county medical societies to express their view regarding the practicality of the suggestions of the Governor's Health Commission. The testimony which they took filled 16,000 typewritten pages, whose substance was summarized in a report which was published in the *NEW YORK STATE JOURNAL OF MEDICINE* of January first, 1932. This report was considered at a special meeting of the House of Delegates on January 14, and was approved with little or no change, as is shown by the minutes which are published in the *Journal* of February 15, 1932, pages 213-225. The report of the committee and the minutes of the House of Delegates constitute the authoritative opinion of the medical profession of the State of New York so far as any group of physicians may reflect the attitude of those whom they represent.

The members of the committee and the House of Delegates were in general agreement with the four basic principles assumed to exist by the Governor's Health Commission; but they kept in mind certain qualifications and explanations of their own interpretation of those principles:

1. While physicians recognize the responsibility of lay officials in public health, they are willing and desirous that their medical societies, through accredited representatives, shall advise public officials, just as individual physicians advise individual patients. Responsibility for giving advice rests upon the physicians, or their societies; the decision regarding action to be taken rests upon the patients or the officials.

2. Provision for medical care shall not include the development of a system of family doctors paid by the State, as in Germany and England. Whatever the system of medical administration, the actual care of the sick requires the contact of an individual doctor with each individual case. Physicians insist on the preservation of the individuality of both the doctor and the patient; but they also insist on the observance of certain standards in both science and methods.

3. While physicians believe in the principle of home rule, and are opposed to the exercise of drastic mandation by the State over local municipalities, yet physicians also recognize the necessity of the observance of standards of practice, administration, and conduct of State-wide application. The happy coordination of voluntary standards with mandation will depend largely on diplomacy applied to each individual case.

4. Physicians agree that it is possible for a group of thoughtful men to devise a practical system of health administration suited to present conditions; but they have an opinion regarding the personnel of that group. They believe that it should not be composed of public health administrators only, nor, on the other hand, of practising physicians only. Public health administrators form one army which is attacking disease, while practising physicians form another independent of the first. Action, effective and happy, will begin when the two armies act in coordination, with a common plan and understanding.

The Governor's Health Commission and the committee of the Medical Society of the State of New York, have studied the subject of health administration from the standpoint of two independent armies. There is no indication that either army will engulf or displace the other; there is every indication that each will conduct its departments of intelligence and planning with the full knowledge and cooperation of the other.

STANDARDS OF MEDICAL ARTICLES

Medical journals frequently publish the standards for judging the availability of articles submitted for publication. There are rules for the form of the manuscript,—it is to be written with a typewriter, double spaced, and on only one side of the sheet. But if this rule were enforced, some excellent papers, especially cast reports, would be rejected. Some authors do not have the time, opportunity or inclination to have their papers typed by an expert.

Some journals require their contributors to follow certain medical dictionaries in spelling, capitalization, and punctuation, but not the least of the difficulties in the enforcement of this rule is the disagreement among the dictionary makers, and even the changing standards adopted by the dictionary makers in successive editions.

The editors of the *NEW YORK STATE JOURNAL OF MEDICINE* would prefer that the outward form of the manuscript should be such that the printer can follow in every detail. But after all facts are what are desired, and if they are pertinent, they will be used no matter what their form of transmission may be. The editors are always ex-

pected to exercise their prerogative to edit, abstract, and rewrite the items which are included in news notes and reports. The editors are also gratified at the cordial response of contributors of scientific articles to suggestions regarding changes in the form of their papers.

Each journal is adapted to a certain class of readers. The question uppermost in the minds of the editors of this Journal is "Will the articles help the general practitioner to practice medicine?" The family doctor, for example, is interested in reports of cases rather than the literature of diseases, and he will profit by the positive rather than the negative features of a case. He is likely to be disappointed if the article does not report a series of cases illustrating the salient points of a disease including even the failures and confusions in diagnoses. Medical editors as well as readers are prejudiced against articles written from books rather than actual experience.

A medical editor always likes to have on hand a number of short snappy, clinical reports from half a page to two pages in length which he may use in fitting the articles to the printed page.

LOOKING BACKWARD

This Journal Twenty-Five Years Ago

Definition of the Practice of Medicine. The Education Law of the State of New York, Section 1250, defines the practice of medicine as follows:

"A person practices medicine within the meaning of this article, except as hereinafter stated, who holds himself out as being able to diagnose, treat, operate or prescribe for any human disease, pain, injury, deformity or physical condition, and who shall either offer or undertake, by any means or method to diagnose, treat, operate or prescribe for any human disease, pain, injury, deformity or physical condition."

This Journal of March, 1907, comments on a decision of the Appellate Division of the Supreme Court, affirming a conviction for the illegal practice of medicine, and says in the course of a lengthy opinion:

"The appeal was based upon the contention that he was not guilty of practicing medicine within the meaning of the law, in that he neither

gave nor applied drugs or medicines or used surgical instruments. The judgment of the Appellate Court is, that, to confine the definition of the words 'practice of medicine' to the mere administration of drugs or the use of surgical instruments would be to eliminate the very cornerstone of successful medical practice, namely, diagnosis. This court holds that it would rule out of the profession the eminent men whose work is confined to consultation and diagnosis. Diagnosis is an integral part of both the study and the practice of medicine. The court, citing the instance of consumption, which may, if discovered in time, be arrested and eradicated by simple hygienic treatment, and that in the treatment of this disease drugs have been practically given up propounds the question, 'Would the physician, in such a case, who by his skill discovered the incipient disease, advised the open-air treatment and refrained from administering drugs, not be practicing medicine?'

MEDICAL PROGRESS

The Acidosis Treatment of Inoperable Malignant Tumors.—Willy Meyer, writing in the *American Journal of Surgery*, January, 1932, xv, 1, states that in his recently published book on "Cancer," he attempted to show that for inoperable cancer acidosis is the remedy. He expresses the opinion that the alkalosis in the cancer patient has been turned into acidosis by fever, Coley's fluid, starvation, artificial hyperemia, induced inflammation, the administration of parathyroid extract, etc., This theory has been worked out experimentally and applied clinically by B. Fischer-Wasles in Germany. Its principal features are the breathing, by means of a tight-fitting mask for two to four hours daily, of a gas mixture composed of pure oxygen plus 4.5 per cent carbon dioxide, combined with intensive deep x-ray therapy of the primary tumor and of its metastases after the Holfelder depth-irradiation method; the administration of large quantities of hydrochloric acid, in liquid form or in tablets, three times daily, and, when indicated, ultraviolet irradiation of the entire body for the purpose of activating the reticulo-endothelial system. Meyer describes in detail a case of inoperable cancer, demonstrated at exploratory operation, in which this treatment resulted in an apparent cure, and refers to other cases in which similar results were obtained. He expresses the opinion that further clinical experience will likely demonstrate that the combination of this acidotic treatment with other methods which are known to have favorably influenced inoperable malignancy will be of benefit.

Besides the deep x-ray treatment he mentions particularly prolonged artificial (synthetic) fever. A high frequency apparatus for this purpose is now on the market. Meyer believes that cancer is a systemic disease, is not infectious, and that it can grow in an alkaline medium only. Alkalinity in conjunction with other causes favors the appearance of the tumor whenever a chronic local irritation is present. As a prophylactic measure local stasis must be prevented at all hazards. Local stasis, with its inevitable consequence of local coagulation of blood and of lymph, favors the formation of a focus, which in turn causes the formation of cancer. Malignant tumors do not occur, or at least very exceptionally, in continuously active organs with a massive circulation of blood and lymph. The biological acidosis treatment of inoperable malignant tumors, as described here and in the author's book, must be worked out further by cooperative efforts of the medical and affiliated professions.

Recklinghausen's Disease with Paraplegic Syndrome.—An unusual case of Recklinghausen's disease is described by Benedetto De Luca, in the *Riforma medica* of November 9, 1931, in which the symptoms unmistakably pointed to an involvement of the spinal cord. The patient, a man of 32, had observed the first cutaneous pigmented spots of the disease at the age of 14, with a fibrous nodule here and there. About 4 years before the fatal termination of his malady, he began to have a sense of weakness and pain in his legs, which was followed some months later by motor disturbances so severe that he was liable to fall suddenly when a leg, more usually the right, would unexpectedly go out from under him. Paresthesias appeared in his feet, and hypesthesia of the right hand. In the third year functional disturbances of the rectum and bladder appeared, and he became more or less incontinent. At the time of observation he was in a condition of spastic paresis of his lower limbs, and mental examination showed a weakening of his faculties. Tuberculosis and syphilis of the spine could be excluded, and the differential diagnosis was accordingly restricted to the group of tumors. The slow evolution of the disease at once excluded a malignant tumor—carcinoma or sarcoma. On the other hand a diagnosis of neurofibromatosis with spinal cord localization appeared to account for the syndrome present. A few cutaneous nodules excised for biopsy purposes were found to be fibrous nodules rich in vessels and traversed by numerous small nerve trunks, thus confirming the diagnosis of neurofibroma localized in the spinal cord. The patient's life dragged on for another 7 months, during which spastic paresis changed rapidly into flaccid, accompanied by signs of degeneration, until death ensued. Autopsy was refused, but there was every evidence that the case was one of those exceedingly rare ones in which Recklinghausen's disease attacks the spinal cord. De Luca has found only 3 such cases reported in literature. The compressive tumor must have been located in the lumbosacral segments of the spinal cord. While the syndrome suggested an extramedullary tumor making pressure upon the medullary cone, there was nothing to prevent the idea that new growths had developed within the nervous tissue of the cord itself. In any case compression had caused destruction of nervous tissue, and accounted for the spastic paraparesis which progressed to flaccid paraparesis. The only treat-

ment possible is operative, and in this case the patient's cachectic condition made such a course out of the question

Mistakes in the Diagnosis and Treatment of Syphilis—During the past three years there have come to the attention of Austin W. Cheever and William D. Wheeler over a hundred mistakes in the diagnosis and treatment of syphilis for which there was no reasonable justification. After citing illustrations of such errors, the authors suggest that intensive propaganda by medical schools, public health institutions, hospitals, and other agencies is essential to acquaint physicians with the methods of modern syphilology. The following list, headed "Lest We Forget" might be distributed to every physician to be kept on his desk.

"1 Consider every genital ulcer as syphilitic unless definitely ruled out by repeated dark field examinations

"2 Remember that extragenital chancres are not uncommon and may be located any where on the body

"3 Bear in mind that a chancre in a woman may be located in the vagina. A painstaking thorough search should be made in all cases

"4 Have routine laboratory tests, such as the Wassermann and Hinton, made on the blood of all your patients, and don't forget that one negative test does not rule out syphilis

"5 Have the blood of every pregnant woman examined for syphilis in early pregnancy. A positive blood test would indicate immediate treatment for the expectant mother and incidentally for the fetus

"6 The time to discover a congenital syphilitic is before the syphilitic is born, that is, treating the syphilitic mother early in pregnancy, all through pregnancy, and then continuing the treatment of the child for a number of years

"7 Treatment in all cases of syphilis should be prolonged, intensive when necessary, and always in keeping with modern procedure and progress. One negative blood test during treatment does not mean a cure. About two to five years are necessary before a probable cure can be effected. In most cases lifetime observation is advisable

"8 Examination of spinal fluid is essential in every case of syphilis and is often the only means of detecting incipient neurosyphilis

"9 Always suspect syphilis. In any of its stages it may simulate other diseases

"10 Whenever in doubt concerning the diagnosis of syphilis consult a syphilologist"—*New England Journal of Medicine*, December 24, 1931, cv, 26

Study of a Case of Parathyreoprivic Tetany.—Marcel Labbé, R. Boulin, and A. Escalier have been able to follow up over a long period, not only clinically but also from a biochemical and a chronaxial standpoint, the case of a man of 22 who had an acute spontaneous attack of tetany a week after a thyroidectomy was performed. He remained in a state of chronic latent tetany in the course of which tetanic contractions could be reproduced by the hyperpnea test. The biologic reactions studied at the moment of the crisis of tetany (hyperalkalosis, reduction of calcium, exaggeration of chronaxia) were characteristic. Treatment by calcium chloride and injections of parathyroid extract produced an excellent result, such that provoked crises of hyperpnea no longer evoked crises of tetany. The patient remained, however, in a state of latent tetany one year later, as was shown by biochemical examinations, by the value of the chronaxia, which was clearly increased, and lastly, by the ease with which an attack could be rapidly reproduced at will. This was a state of alkalosis, which became exaggerated during the attacks. The alkaline reserve, which is sometimes rather high during the period of latency, was lowered during the hyperpnea tests: the blood pH rising from 7.31 to 7.61 at the moment of the crisis, and the alkaline reserve dropping from 65.1 to 55.36 volumes of carbon dioxide per cent of plasma. During the attack the urine showed increased alkalinity. The blood calcium was generally lowered. In the chronaxial disturbances it was observed that there still existed, during the period of latency, a manifest increase, stronger on the right side, where the contractures predominated, and that it was of triple or quadruple order. In the most recent test, however, the chronaxia had begun to fall, a small fall being followed by a less rapid rise than before, in a longer curve, although reaching the same height, with the last part of the curve remaining the same. It seems, therefore, that a certain improvement was shown by this less rapid increase of chronaxia, suggesting the possibility that a compensatory hyperplasia had permitted the organism to recuperate a part of the parathyroid secretion and its endocrine equilibrium, although such compensation was far from being complete. The authors call attention to the great value of the examination of the chronaxia, for the fineness with which it reveals the most minute latent troubles.—*Revue française d'endocrinologie*, October, 1931

Injuries to the Crucial Ligaments of the Knee-Joint—Ivar Palmer reports two cases of injury to the crucial ligaments of the knee-joint and suggests a new method of repair of

the posterior crucial ligament. The first case was that of a motorcyclist who sustained a blow on the front of the leg with the knee flexed. Very soon afterward a positive "drawer sign" backwards was obtained spontaneously on active flexion of the knee-joint. The diagnosis of rupture of the posterior crucial ligament was confirmed by the roentgenogram. Cases of injury in which it has been possible to make the diagnosis immediately after the accident have not heretofore been published. The second patient was admitted five weeks after the accident and then presented signs suggestive of a lesion of the menisci. The "drawer sign" could not at first be obtained, but became evident under anesthesia, being positive forward. Arthrotomy revealed rupture of the anterior crucial ligament. These cases emphasize the following points. The only typical sign of injuries to the crucial ligaments is the so-called "drawer sign." This cannot generally be demonstrated until hemarthrosis and muscular contraction have disappeared, but it may also be positive for a short time immediately after the trauma. Occasionally the sign can be demonstrated only during anesthesia. The author suggests a plastic operation for replacing the posterior crucial ligament. He makes use of the lateral half of the semimembranous tendon split lengthwise; the muscular attachment on the posterior surface of the tibia is found on the medial side of the lower attachment of the posterior crucial ligament. On the lateral aspect of the muscular attachment, close to the posterior tibial border, the tendon is guided with retained lower attachment through the posterior wall of the capsule, then retrosynovially upward to a drilled canal through the inner femoral condyle which emerges into the intercondyloid fossa at the site of attachment of the posterior crucial ligament, *i.e.*, immediately behind the line of attachment of the synovial membrane. It is then fixed to the internal lateral ligament on the outer side of the internal femoral condyle. Judging from his experiments on the cadaver, the author thinks that this operation should yield functionally good results.—*Acta Chirurgica Scandinavica*, December 3, 1931, lxix, 1.

Treatment of Chronic Deafness with High Frequency Sound Waves.—Hamm reports improvements in this method which have now made it applicable to many cases of otosclerosis. The prognosis is unfavorable only where the Rinn test is absolutely negative. This treatment, which he has previously described, must never be employed for less than 4 weeks to 2 months. After improvement has set in, a weekly or biweekly treatment is still desirable for 1 or 2 months more. The usual treat-

ment is 2 or 3 sittings a week, of a quarter of an hour each, one ear after the other. Longer sittings have no advantage over these. The external ear is thoroughly cleaned and dried before the irradiation begins. The largest possible speculum should be used which can be inserted without pressure upon the tympanum. It is advisable to use the highest frequency (250,000 Hertz), as this gives more lasting results. With the exception of one case, in which this frequency was followed by tinnitus, there have been no disadvantageous results, even children bearing it without reaction. In children the tonsils should first be removed, since where this is not done, the deafness is likely to return the next time the child takes cold. Hamm has been using this method, carried out with a Mülwert apparatus, for over 2 years, and he reports that he has a number of patients whose improvement has persisted for 2 years without relapse and without renewal of treatment. As a general precaution, he would give a repetition of the treatment after a lapse of 6 months, as he has seen cases in which the result of the second treatment was successful where the first had failed. Contrary to Mülwert's own experience, he has demonstrated that the irradiations penetrate not only the tympanum but also the intact skin. The difference in these experiences is due to the fact that Mülwert's observations were made on cadavers, and Hamm's upon the living ear. Even a tympanum pathologically changed by old age presents no obstacle to the rays. One of his illustrative cases is that of a physician who had been suffering with gradually increasing impairment of hearing for 10 years, which became complete deafness after an attack of grippe in February, 1931. After a 6 weeks' treatment he could hear a watch at 2 cm., whispering at 12 cm. and conversation at 65 cm. distance, and reported 5 weeks later that the improvement had been maintained. Such cases are frequent.—*Klinische Wochenschrift*, December 5, 1931.

Dehydration Fever of the New-Born.—F. H. Clark analyzes 60 cases of dehydration fever of the new-born, also known as inanition fever, transitory fever of the new-born, thirst fever of the new-born, thirst hyperthermia, and exsiccation fever. The highest fever recorded in this series was 106.8° F. The greatest number of cases occurred in April and November. The summer incidence was lower than the winter. The dryer heat of artificial heating in the winter months probably contributes to the higher winter incidence. Of the 60 cases 37 were males, with an average weight of eight pounds and five ounces, and 23 females, with an average weight of seven pounds and eight ounces.

The average loss of weight was 15 ounces. The largest loss of weight was two pounds and four ounces. Of the 60 cases 38 were the infants of primiparae, 12 were second born. The greater difficulty of labor in primiparous patients is contributory. The part that the type of delivery plays does not seem to be significant. Cesarean babies appear to be affected because of the shock of the operation delaying the milk supply. The symptoms and signs appearing most frequently in the mild cases are moderate fever, hoarse cry, dry and lusterless mucosa of the mouth and throat, clean red tongue with prominent papillae, and dry, wrinkly skin. The severe cases are characterized by high fever, squeaky or no cry, hyper-tonicity and dusky color. The treatment consists in supplying fluid, preferably by mouth. The author uses a 5 to 10 per cent lactose or dextri-maltose solution. In extreme cases and those in which the infants do not suckle well, this may be augmented by saline solution subcutaneously and by enema, leaving in two or three ounces if possible. It should be seen that the infant gets sufficient breast milk, and, if not, the intake should be complemented with a formula. The overheating of nurseries should be more carefully guarded against, particularly in unseasonably warm waves. The humidity should be watched in winter. Large babies particularly should be given fluid freely during the first two or three days of life following the usual nursings. Infants of average size, losing over 12 ounces, should be given complementary formulas.—*Archives of Pediatrics*, December, 1931, xlviii, 11.

The Frequent Occurrence of Abnormal Cutaneous Capillaries in Constitutional Neurasthenic States.—In a study of 500 cases showing no evidence of organic peripheral vascular lesions other than perhaps a sclerosis commensurate with age, J. Q. Griffith, Jr, found 31 cases in which the diagnosis included a functional neurasthenic condition. The method employed to determine the capillary condition was that of examining microscopically the skin just back of the finger nail, after covering it with cedar oil to render the epidermis transparent. Of the 500 cases 8 showed a definite morphologically abnormal capillary picture, and these 8 were included in the 31 cases with a diagnosis of functional neurosis. In the 8 cases showing the abnormal capillary picture the diagnoses were as follows: simple psychoneurosis, 2; psychasthenia, 1; neurocirculatory asthenia, 2; neurasthenia and hyperthyroidism, 1; vasomotor neurosis and essential hypertension, 1; infectious arthritis and infected tonsils, 1. In the last case the history indicated a definite neurosis. In all the 8 cases the functional

neurasthenic quality had been present from childhood and peripheral vasomotor instability was a prominent symptom. Of the 31 patients with functional neuroses, 23 were found perfectly normal as concerned the nail-bed microscopy, and their neuroses dated from an emotional or psychic shock and not from early childhood. Griffith makes the deduction that in the absence of any recognized peripheral vascular disease, abnormal cutaneous capillary configurations, as seen in the nail-bed, are most apt to occur in conjunction with neurasthenic states dating from early life and with constitutional nervous instability.—*American Journal of the Medical Sciences*, February, 1932, clxxxiii, 2.

Endometriosis.—Halbert G. Stetson and John E. Moran call attention to the fact that the largest percentage of endometrial tumors have occurred in the ovary, the retrogenital space, the Fallopian tubes, and the uterus. Other localities are the umbilicus, small intestine, rectum, broad and round ligaments, groin, cervix, vaginal wall, appendix, wall of the bladder, and the epiploic appendages. A few have occurred in an abdominal scar following operation. Endometrial lesions have commonly been mistaken for carcinomas, which they resemble in the routes of dissemination. Graves has reported four cases in which oöphorectomy resulted in retrogression of ectopic foci. This type of treatment seems feasible in rather diffuse endometriomatous lesions where extirpation of the mass is impossible. The authors' first case is of this kind. The patient, a woman aged 33 years, developed symptoms of intestinal obstruction. On opening the abdomen a cystic tumor presented at the site of the incision. It was apparently of parovarian origin. The tumor and left ovary and Fallopian tube were dissected out, when it could be seen that the sigmoidal obstruction was due to a circular growth at the junction of the sigmoid and the rectum. It was felt that it was impossible to extirpate the growth. A left inguinal colostomy was made and the abdomen was closed. Later the right ovary, Fallopian tube, and an ovarian cyst were removed. The patient recovered and is well in every way five years after the operation. She has one movement daily through the colonic fistula and a small normal bowel movement each day without discomfort. The second case was one of endometrioma of the umbilicus in a patient 35 years of age. The preoperative diagnosis was probable infected urachus. The umbilicus was removed. The specimen consisted of a piece of skin, measuring about 2 by 2 cm. with an umbilicated center, together with the underlying tissue, to a depth of about 1.5 cm. Sections showed fibrous tissue with small pockets of gelatinous material.—*New England Journal of Medicine*, January 14, 1932, cxcv, 2.

LEGAL

A CHALLENGE TO THE BAR

By LORENZ J. BROSNAN, Esq.

Counsel, Medical Society of the State of New York

The members of the medical profession, when brought into personal contact with the operation of our legal machinery, are often amazed at its delays and technicalities. It is logical that they should compare the marvelous progress in their own profession with the lack of progress on the part of the legal profession. As intelligent observers of the workings of our courts, many of them have given voice to the very just charge that changes are needed in the legal machinery of our courts and that they should be made. The law too often provokes the well-founded criticism that a party to a lawsuit is deprived of a fair and prompt determination of the issues therein involved. The answer is frequently given that such delays and injustice are unavoidable and must be expected as the practical working out of controversies in our complex civilization. Suggestions of change are often silenced by the statement that the present legal machinery has been long organized in its present form, and that it must not be altered in its traditional manner of operation for to do so would destroy the very root of our judicial system.

What we have said thus far will serve to introduce a scholarly and interesting paper by Judge Frederick E. Crane of the New York Courts of Appeals, read before the Bar Association of the City of New York recently. His remarks will be of interest not only to lawyers and judges, but to those outside the profession as well. Judge Crane's paper is filled with plain, ordinary common-sense. In it he points out the need for constructive changes in the law today. We believe this paper to be of such interest that we intend to quote at length from it in this editorial.

The learned Judge points out that " . . . in this day of change and of challenge our own system of administering law is being questioned. The idea is being spread through address, radio and press that somehow something is wrong with our system of justice in this land. It is being challenged. Heretofore the law threw down the gauntlet; it challenged the divine right of kings and the feudal system; it sought to establish and did establish the security of life, liberty and property of the citizen, and the constitutions and statutes under which he might pursue his individual choice of occupation and his own happiness. Now, however, it is said the law has become static; justice cannot be speedily obtained, if ob-

tained at all; the law in its turn is being challenged."

Every practicing lawyer will be in entire sympathy with Judge Crane when he discusses the admitted fact that many controversies which were formerly decided by the courts, have now entirely passed into the hands of arbitration boards, commissions and other bodies selected by the litigants themselves.

"Merchants no longer wait upon the tedium and the uncertainty of legal proceedings. With courts established and judges paid high salaries to decide the disputes between business men, they will have none of it, and have passed arbitration laws whereby their disputes and their agreements will be settled by laymen outside of the court. So we now have not only in the state, but in the nation, compulsory arbitration law. Think of it, the law gives the judge, the jury and volumes upon the technical law of contract, shelves of books upon the law of evidence, and the merchants of this land have arrived at the point where they want none of it; they are through with it; it is useless, too cumbersome, has become like the laws of France before the French revolution—a complication beyond solution. The members of the Produce Exchange, of the Stock Exchange, silk and woolen merchants now take their differences to a layman, a silk merchant, grain merchant or any other kind of business man who hears both sides without any regard to the rules of legal evidence or to substantive law regarding acceptance or rejection or the passing of title, and decides what one man shall pay the other. Under this arbitration system now in vogue by the exchange and by the business men, we do not find that the heavens have fallen or that the results are to blame for the business depression. Our system is being challenged.

"Over in Kings County they have gone so far as to establish a Good Will Court, a voluntary organization which meets every Monday night to settle all kinds of disputes which may be brought before the Court by agreement of the parties. It is presided over by different judges and referees each week. In the past three years, so I am credibly informed by Municipal Court Justice Nathan Sweedler, it has disposed of over four thousand cases.

"Before this court, settlements have been made running as high as six hundred or seven hundred dollars in a case. The judges have included

priests, ministers, bankers, university professors professors of sociology, both men and women"

Judge Crane discussed the interminable delay encountered by litigants in certain of our courts, and commented

"It is about time that we lawyers and judges commenced to clean up and tried to find some remedy for the trouble. We have had much to say this year about our Federal Constitution and look to it as the main guarantee for our civil rights. Like provisions dealing with individual rights are embodied in the state constitution. But what is the good of guaranteeing rights if there is no means of enforcing them? Wrongs which may persist for a lifetime deny the rights guaranteed. A right needs a speedy means for enforcing it, and a wrong, immediate power to overthrow it. Delay is the denial of one and the encouragement of the other. There is nothing new in this idea which is as old as the hills. Repetito mater studiorum

"The lawyers tell me that their clients are obliged to settle their cases at nominal figures, because they are unable to wait for litigation, wait until their case is reached for trial. Financial reasons demand a sacrifice for their rights. As likely as not after a verdict a case is carried up on appeal and reversed either by the Appellate Division and the Court of Appeals, and the same procedure starts all over again. Only those who seek delay or else have money or have some strike litigation can afford to wait and take chances."

A constructive suggestion was voiced by the speaker with respect to the disposition of the thousands of automobile cases that clog the court calendars, and present a real problem in practically every county in our State. He said

"The thought has occurred to me, however, that we might be able to extend the Compulsory Arbitration Law to include a certain number of our tort actions. The number of automobile accident cases has added materially to the number of the cases upon our calendar. While the parties might agree to have such a case heard by a referee, they seldom, if ever, consent to such a procedure. As in arbitration upon contract, so in tort, to make it effectual, there must be some method of compulsion. In the ordinary negligence case the constitutional right to a trial by jury bars the way to forcing the parties to try their issues before selected arbitrators or referees. However, I am under the impression that this constitutional provision will not stand in the way of compelling defendants to arbitrate in automobile cases. The Court of Appeals held in *People v. Rosenheimer* (209 N. Y. 115) that the operator of a motor vehicle exercises a privilege, which may be denied him, and not a right, and in a case of a privilege the Legislature may prescribe on what conditions it shall be exercised. We now tax the owner of an automobile and re-

quire him to take out a license. We also require him to tell the party injured who he is, and to also inform the police authorities, all of which is contrary to certain constitutional rights against self-incrimination. What is to prevent the Legislature from also requiring the owner of an automobile, in taking out his license, to consent to arbitration in case of accident, and also to compel the insurance company insuring such an owner to have such a clause in their policies? We now require the insurance company to put a clause in their policies agreeing to pay the judgment even if the insured be insolvent (section 109 of Insurance Law). At least we would have taken one step toward ridding our calendars of these automobile accident cases. I doubt whether the Legislature could compel the injured party, the plaintiff in these cases, to consent to arbitration (Sec. 2, Art. 1, New York State Constitution), but many would so consent if the defendants were compelled to arbitrate, rather than wait years for a trial. Public sentiment and the attitude of the Bar would soon compel these plaintiffs to seek this relief. And what a speedy disposition there would then be of all these automobile accident cases when the court could appoint arbiters without limit—a lawyer, a doctor, a layman—who would dispose of the case as satisfactorily, yes, more satisfactorily than most of the courts and juries."

Endless appeals which often tie up litigants for years and result in many instances in nothing but delay of the trial or fruitless retrials, were discussed at some length by Judge Crane, and part of his remarks with respect thereto were as follows

"A trial is a matter of right, and an appeal is a matter of favor. The appeal should be the exception and not the rule. Litigation, unless for some very good reason, should end with the trial Bench. Speaking for myself, and for myself alone, and not in any way intimating that I am expressing the views of any other member of my court, let me say that the presumption on appeal should be that the order of the judgment is right unless some very good reason can be shown to reverse it. Cases should not be obliged to run the gauntlet, submit to re-examination, to substitute able appellate judges as counsel for the parties. Unless it is pointed out or clearly appears that serious error has been committed, some injustice done, or a fundamental principle denied, there should be an affirmance. So called interesting cases many times add to the technicalities instead of the usefulness of the law. The main view should be to end litigation unless something decidedly has gone wrong. I think the day is fast approaching, if not already here, when technical errors in the admission or rejection of evidence are brushed aside, if the result appears to be right. The attitude today upon the part of the

profession is an impatience with motions or technical practices which delay the trial of the cause. Hardly any case of importance can be tried without some error."

"It makes a great deal of difference, however, to some unfortunate litigant, who has only one case in a lifetime, which involves his entire livelihood or his reputation or his fortune, if he has to wait four years before his case can be heard. It is a denial of justice and of all the rights guaranteed him by our constitutions. Far better that his case be heard speedily and disposed of than that some very fine opinion be handed down by an appellate court, meeting with the approval of the press, of schoolmasters and publicists."

"A very small proportion of the cases ever go up on appeal. The main or most important thing in the administration of justice, outside of fairness and impartiality, is a speedy hearing of the cause. Mark you, the pages of history show more than one instance where the impatience of a people has broken through the refinements and delays of the law to establish a cruder but a more speedy tribunal for the hearing of their causes. The court, after all, is but a substitute for force, and far better is it that a litigant be heard by one not too learned in the law than not be heard at all."

The learned Judge then took up and considered at some length the abuses that are apparent, even to a layman, in the trial of many of the actions in

our courts—the unnecessary length of time frequently taken by counsel in the selection of a jury, the endless and fruitless cross-examination of witnesses are the subject of pertinent comment. Judge Crane suggests that the trial court should be given more power to restrict such practices, and that the exercise of such power should be supported by the appellate courts unless the matter presents a gross abuse of discretion. It is to be hoped that not only Bench and Bar, but those outside the profession as well, will hearken to the concluding observation of Judge Crane when he said:

"Thus men differ, as you will differ with many, if not most, of the recommendations I have made tonight. We need not fear our differences. No danger will ever come to this country or to our administration of law through our differences. Wide-awake, thinking men are bound to differ. Our danger lies in our indifferences. The whole point of my address tonight is to beg of you not to be indifferent to this restlessness upon the part of our people in this city without administration of law, and that we seek with the exercise of all our powers for a remedy to the delays in litigation."

"May I close with these words from Arthur Stanley Eddington, professor of astronomy at Cambridge, which are as true regarding us and the law as of the scientist and his work: 'You will understand,' said Eddington, 'the true spirit neither of science nor of religion unless *seeking* is placed in the forefront.'"

MALPRACTICE CLAIMED IN TREATING INDUSTRIAL ACCIDENT

The plaintiff in this case, while at work in his employment as a laborer on a construction job, was struck in the leg by an iron beam and suffered a fracture of the femur. He was taken to a dispensary and there given first-aid treatment by the defendant doctor and then removed to a hospital where, under the care of the same doctor, the fractured femur was reduced and traction applied. The patient remained in the hospital for a considerable period of time and during the entire period of hospitalization he was an intractable patient, refusing to obey the orders and instructions of the physicians and nurses, removing traction from his leg, and tearing away the splints and later the plaster casts.

Subsequently an action was instituted against the defendant, claiming that due to his negligence the plaintiff's leg was shortened about 1 3/8 inches and that the leg was caused to be weak, deformed and crippled. The answer interposed on behalf of the defendant

was a denial of all allegations of negligence and contained the special defense that the plaintiff had already received complete compensation for his injuries from his employer under the Workmen's Compensation Act.

The action duly came on for trial before a judge and jury, and at the end of all the proof on the part of the plaintiff a motion was made by counsel for the defendant to dismiss the complaint. The court directed judgment in favor of the defendant without requiring him to put in any evidence as to whether or not he was negligent, upon the sole ground that the plaintiff had received an award made by the State Industrial Commission pursuant to the Workmen's Compensation Act for his injuries, which award included all the injuries sustained by the plaintiff, he having failed to establish by his testimony that he suffered any injuries in addition to those sustained from the accident which occurred during the course of his employment.

NEWS NOTES

COMMITTEE ON LEGISLATION

BULLETIN NO 2

February 3, 1932

Since our last bulletin the following bills have been introduced:

Senate Int No 410—Williams, to amend the Education Law relative to medical inspection by making the section apply also to schools other than public schools and for transferring duties of education boards and trustees to health authorities. Senator Williams in this bill has brought up the question again as to whether school medical inspection should not be a responsibility of the Department of Health rather than the Department of Education. The Governor's Special Health Commission debated this subject for quite a while and in their report state that "school health service logically should be a continuation of health services for infants and pre-school children. Records of examinations and medical history should be continuous."

Senate Int No 415—Pitcher, concurrent Assembly Int No 591—Austin, would amend the Mental Hygiene Law by providing among other things that license issued to private institution for care or treatment of persons with mental disorder or defects or for mentally incompetent epileptics may be for a definite period. This bill was drafted by the Department of Mental Hygiene and is intended primarily to clarify the language in the law at present.

Senate Int No 417—Lord, Assembly Int No 483—Jenks, to amend the Tax Law by providing property held for hospital purposes in name of corporation organized to manage hospital for benefit of city shall be exempt from taxation to same extent as property of corporation organized exclusively for hospital purposes.

Senate Int No 444—Hanley, Assembly Int No 526—Ostertag, would authorize a superintendent of a public general hospital to maintain a revolving petty cash fund not to exceed \$100.00. The object of this bill is to assist particularly the state aided hospital at Warsaw, but probably will be applicable to all of the state-aided hospitals.

Senate Int No 450—Burchill, amends the Public Health Law, providing certificate of birth must contain photograph of finger prints of mother and foot prints of child. Last year Senator Love introduced a bill that differed from this one in stipulating that such procedure was to be followed only if the child is born in a hospital.

Senate Int No 467—Wheatley, Assembly Int

No 604—Otto, to amend the Public Health Law by striking out limitations on compensation of health officers. This bill originated with Mr. Otto. It has been amended so that it now reads that 15c per capita shall be the maximum amount paid a health officer. It is only a few years since this law requiring a minimum of 15c per capita was enacted and it does not seem to us that times have changed so much that it should not be considered a maximum amount.

Senate Int No 533—Twomey, Assembly Int No 598—Gimbrone, to amend the Education Law relative to the sale of poisonous or habit-forming drugs or chemicals. Messrs Twomey and Gimbrone had this bill last year. It passed the Senate and was referred to the Assembly Education Committee, from which it never emerged.

Senate Int No 546—Nunan, Assembly Int No 684—Esquirol, would amend the Workmen's Compensation Law by providing compensation shall be payable for disabilities or death of an employee resulting from any occupational disease. Last year this same bill was carried by Senator Love and Assemblyman Esquirol.

Assembly Int No 464—Coughlin, to amend the Workmen's Compensation Law by adding to list of occupational diseases for which compensation is payable, all disabling diseases and disabling illnesses. You will recall that Mr. Coughlin had this same bill last year.

Assembly Int No 511—Cuvillier, to amend the Penal Law by fixing penalty for torturing and injuring animals, imprisonment for not less than thirty days and not more than one year. The object of this bill, Mr. Cuvillier says, is to "put teeth" in the law so that persons who deliberately run down dogs or other animals with their automobiles shall receive a severe punishment. His attention has been called to several instances where animals have been mistreated, and he feels the necessity of making the law more severe. It is his intention to amend this bill so as to make it clear that it shall in no way be construed as to apply to the treatment of dogs or other animals in experimental laboratories connected with educational institutions.

Assembly Int No 544—Schwartzwald, to amend the Education Law, creating a division of medicinal liquor to which is delegated powers to carry out provisions of proposed law relating to prescription, sale and use of intoxicating

liquors for medicinal purposes and appropriating \$250,000. Mr. Schwartzwald sponsored this same bill last year. It never was reported upon favorably by the Ways and Means Committee, with which it rests again this year.

Assembly Int. No. 584—Theodore, to amend the Workmen's Compensation Law to permit injured employee to provide for his own treatment and care at expense of employer. Mr. Theodore sponsored this bill last year, but it was never reported upon favorably by the Labor Committee, with which it rested.

COMMENTS

We reported last week that Senator Berg had introduced a bill—Senate Int. No. 324—providing that the period for registration of physiotherapists be extended for six months subsequent to May 17, 1932. We understand that a number of physiotherapists claim to have possessed qualifications entitling them to registration in 1926, but neglected to make application, and they have asked Mr. Berg to secure this amendment in order that they can register with the Department of Education. We do not think it wise to open the matter again; it is six years since the period of registration expired.

We also mentioned in last week's bulletin that the Department of Education invited Dr. Johnson

to bring others with him to a conference relative to the proposed bill of the osteopaths. The conference was held and it was reported that the osteopaths contemplate reintroducing their bill of last year with a slight amendment. While no action was taken, it appeared to be the opinion of the physicians attending the conference that the Society would consider it in the interests of the public to oppose the bill as they did last year. It was announced at this conference that the Department of Education contemplates requiring the osteopaths to raise their educational qualifications to the equal of those of physicians, after 1935; that is, students will be obliged to take a two-year college pre-medical course and a four-year regular course. We were informed in the Capitol yesterday that Augustus Downing, Ph.D., lobbying for the osteopaths, was seeking some person to introduce their bill.

HEARINGS

As we announced in our last bulletin, there will be a hearing on the anti-vivisection bill on Tuesday, February 9th, 2:00 P.M., before the Assembly Committee on Codes.

HARRY ARANOW,
JOHN J. BUETTNER,
MARSHALL CLINTON,
Committee on Legislation.

BULLETIN NO. 3

February 10, 1932.

Since our last bulletin the following bills have been introduced:

Senate Int. No. 624—Dr. Love; to amend the Education Law by prohibiting the sale of food in drug stores and pharmacies. This bill is even more drastic than last year's bill, in that it contains this additional sentence: "It shall be unlawful for any druggist or pharmacist to dispense soda water or other beverage on the same day that such druggist or pharmacist dispenses drugs." You may have forgotten that the sentence preceding that is the one to which great exception was taken last year, and reads: "No article of food to be consumed on the premises shall be sold or served in any drug store or pharmacy in the state."

Senate Int. No. 635—Wicks; Assembly Int. No. 793—Austin, to amend the Public Health Law relative to requirements to practice midwifery. The amendment limits the registration of midwives to those who possess a diploma from a school for midwives recognized by the State Commissioner of Health.

Senate Int. No. 636—Wicks; Assembly Int.

No. 792—Austin, is another bill introduced by the Department of Health to amend the Public Health Law relative to district records to be kept by registrars of births or deaths. The principal feature of this amendment is to require that registrars in counties where the public health work is organized under the county health unit plan shall make their report directly to the commissioner of the county health unit.

Senate Int. No. 746—Baxter; Assembly Int. No. 946—Heck, adds new section to the Penal Law, making it a misdemeanor to manufacture, sell or use certain chemical agents classified as a lung irritant, irritating smoke and screening smoke, etc., in gas, liquid or solid form, for use against person or property of another. We haven't seen the printed bill as yet, and, hence, are not in a position to make comment.

Assembly Int. No. 949—Killgrew, would amend the Education Law in regard to the practice of physiotherapy. The amendment consists in adding bacteriology and diagnosis to the list of subjects that an applicant for a license to practice physiotherapy must present a knowledge of, and stating that the method of treatment shall be "only

by means of the use of actinotherapy, hydrotherapy, mechanotherapy, thermotherapy, and electrotherapy, exclusive of the x-ray, and to diagnose and prescribe therefor." It would eliminate from the law the following: "Under the supervision of a duly licensed physician." This bill has been referred to the Committee on Education and no time should be lost by any chairman in acquainting the members of the Education Committee with the point of view of the physicians and the danger that the public would be liable to from permitting these people to practice without medical supervision.

Assembly Int No 975—Garnjost, to amend the Education Law regarding the practice of osteopathy. This is a bill identical with the bill introduced last year and will, of course, be opposed by the Medical Society on identically the same grounds, namely, that osteopaths in the past have not been trained to perform surgery as it is ordinarily construed nor have they had any training or experience in the administration of narcotics, anesthetics or antiseptics, to say nothing of serums, vaccines and antitoxins. Although there are but 362 osteopaths in the state, as we have been informed, we think it exceedingly unwise to jeopardize even such a small portion of the public as may come in contact with these osteopaths, by permitting them to prescribe or administer such powerful drugs, considering that they not only have not had training and experience in their effects upon the human body, but have been specifically trained to believe that they are harmful and possess no virtue. Make no delay in taking up the opposition that you expressed so forcibly last year with the members of the Education Committee, and we may say that there have been very few changes in the personnel of that committee. The white book may be available today and as soon as it is procurable, we shall see that a copy is sent you.

Assembly Int No 996—Stewart, would amend the Penal Law by providing that no hospital supported wholly or partly at public expense shall charge for medical services given while operating a clinic to which public is invited. Last year Senator Howard and Assemblyman Story carried

this bill. When initially introduced, it was construed as retroactive. The bill was amended to correct this and in its final reading was identical with the bill introduced this year.

HEARINGS

As previously announced the Codes Committee yesterday gave a hearing on the anti-vivisection bill. The Anti-Vivisection Society made greater effort in the last year to create sentiment in favor of this bill than in previous years, and submitted petitions said to be signed by 20,000 voters. Dr. Bayne-Jones, Chairman of The Committee on Medical Research, had invited a very impressive group of physicians to assist him in opposing the bill. Among them were Drs. Sondern, John Wyckoff, Allen Whipple, Frederick Tilney, Dr. Canby G. Robinson, of Cornell University, Drs. Simon Flexner, Florence Sabin and Peyton Rous, of the Rockefeller Institute, Drs. Geo. Whipple and John Morton, of the University of Rochester. The committee asked each physician testifying whether, in his or her experience or knowledge, cruel treatment was perpetrated upon dogs, particularly whether dogs were ever operated upon without being properly anesthetized. Naturally, all speakers denied any knowledge of such cruelty. When the proponents of the bill spoke, the committee insisted that as a basic reason for the introduction of the bill they should give at least one specific instance where cruel treatment, as described above, had been given a dog in some laboratory in New York State. Everyone who spoke for the bill admitted to the committee that he or she had no specific knowledge of that character. The committee expressed itself as inclined to believe that there was no need for an amendment to the law unless specific proof could be brought out that violations of the law occurred that could not be convicted.

In closing, may we remind you that the legislature may not be in session long and that what we do must be done quickly.

HARRY ARANOW,
JOHN J. BUETTNER,
MARSHALL CLINTON,
Committee on Legislation

LETTER TO COUNTY LEGISLATIVE CHAIRMEN

February 4, 1932

Dear Doctor

Enclosed you will find the following bills:

Senate Int No 410—Mr. Williams. This bill or a similar one has been before the legislature a number of times, but it carries a little more weight this year because the Governor's Special Health Commission for quite a while considered

the advisability of having the medical inspection bureau removed from the Department of Education and placed with the Department of Health. They did not make such recommendation, but there has been a good deal of sentiment expressed in favor of it.

Senate Int No 415—Mr. Pitcher. This bill was drafted by the Department of Mental Hy-

giene and its prime function is to clarify the law.

Senate Int. No. 444—Mr. Hanley. This bill is drawn to meet a situation that has arisen in the Wyoming County Hospital, which now receives state aid. It probably will be applicable to all state-aided hospitals.

Senate Int. No. 450—Mr. Burchill. Last year this bill was carried by Dr. Love, with the exception that it then applied only to births occurring in a hospital. It would seem to us that it would be very difficult to secure finger prints of the mother and foot prints of the baby in rural practice.

Assembly Int. No. 464—Mr. Coughlin reintroduces his bill of the last several years, making compensable any condition or disease arising out of employment. We have always, as you will recall, opposed the bill on the ground that it would ultimately work a great injustice to the employee.

Assembly Int. No. 511—Cuvillier. Mr. Cuvil-

lier has in mind persons who deliberately run down animals with their automobiles or mistreat them in order to make them "fashionable." He has no desire whatever to have this bill confused with the anti-vivisection bill. Probably it is not wise to have him move it at this time, because the anti-vivisectionists may take advantage of it if it were to come out on the floor.

Assembly Int. No. 584—Mr. Theodore reintroduces his free-choice bill of last year.

Assembly Int. No. 598—Mr. Gimbrone reintroduces his bill on habit-forming drugs. This bill passed the Senate last year, but was lost in the Assembly Education Committee.

Give us your opinion upon the above bills at your earliest convenience.

HARRY ARANOW,
JOHN J. BUETTNER,
MARSHALL CLINTON,
Committee on Legislation.

LETTER TO COUNTY LEGISLATIVE CHAIRMEN

February 15, 1932.

TO COUNTY SOCIETY LEGISLATIVE CHAIRMEN.

Enclosed you will find the following bills:

Senate Int. No. 467, late Print No. 648—Wheatley. You will notice that Mr. Wheatley's amendment is very slight, but it has a very far-reaching effect. He asks that the 15c per capita which now is the minimum amount which health officers are to be paid, be the maximum. This is an unwarranted procedure; nobody believes that the health officers generally are adequately paid now. If there are a few who may appear to be overpaid, we are sure the matter could be corrected if it were called to the attention of Commissioner Parran and the particular board of supervisors.

Senate Int. No. 746—Mr. Baxter has introduced this bill at the request of the state police. It would limit the manufacture and ownership of tear gas to proper authorities. The object is to prevent the gas from being used against the police. We believe it a good bill and should receive our support.

Assembly Int. No. 949—Mr. Killgrew, an Assemblyman from New York City, has chosen to sponsor the physiotherapy bill for this year. You will note the particularly vicious part of the bill is the deletion from the law of that portion which provides that this group of physiotherapists shall not practice except under the supervision of a duly licensed physician. It also adds to the course of studies to be given at New York University to those who elect to take a short course in physiotherapy, the two subjects of bac-

teriology and diagnosis, and then in detail outlines what form of therapy they should prescribe. This is another instance in which an effort is being made to legislate in favor of a few inadequately trained persons. The opposition to this bill should be as definite and vigorous as in past years. We feel certain that the Department of Education will not approve of it and we hope that each chairman will immediately write to his legislators and particularly to those who are on the Education Committee in the Assembly, opposing the bill on the ground that it would be doing an injustice to the public and would be equivalent to lowering the educational standards established by the Regents.

Assembly Int. No. 975—Mr. Garnjost has introduced the osteopathic bill. You will note that it is identical with the bill of last year, except that three words—"or other tumor"—have been introduced following the word "cancer," line 17, page 2. The surgical aspect of this bill is sufficiently vicious in itself to bring forth all the opposition that persons interested in public welfare can muster, but the permission to use drugs is even more vicious. Osteopathic schools published in their catalogs, until this year, that drugs have no place in the practice of osteopathy. If men were trained in that sort of atmosphere, they cannot, in so short a time, adapt themselves to an atmosphere in which a group of drugs as powerful as the narcotics can become safely serviceable.

The osteopaths last year, in urging the passage of their bill, repeatedly stated that they take the same examinations as physicians and, therefore, should be granted the same privileges. This is

another of those half-stated truths. They do take identically the same examinations as physicians, but a candidate for licensure in osteopathy is not

which this bill would permit osteopaths to use, although they have not had adequate training in their uses and dangers:

Narcotics

Paraldehyde
Opium
Heroine
Laudunum

Tronal
Urethane
Morphine
Bromides

Veronal
Chloral
Codeine
Scopolamine

Anesthetics

Chloroform
Ethylene Gas

Erysipelas Antitoxin

Diphtheria Antitoxin
Tetanus Antitoxin

Gas-Gangrene Antitoxin
Botulinus Antitoxin

required to present for entrance to an examination, the same qualifications as required of candidates for the degree of M.D.; for instance, osteopaths are not required to take two years' pre-medical work, nor to give evidence of having taken two years in the study of drugs. Please bear this distinction in mind.

Another item of misinformation that circulated very extensively last year is to the effect that Augustus Downing, who lobbies for the bill, is an M.D. No longer ago than within the last few days, a letter came to our attention, signed by the chairman of the Assembly Committee on Public Education, in which he expressed surprise that Dr. Downing is an M.D. and yet approves the bill. Dr. Downing is *not* a Doctor of Medicine, nor does he have that degree.

Following are a few of the dangerous drugs

Again may we suggest that you pass this information to as many prominent lay persons as you can and urge them to indicate their feelings to, first, the members of the Education Committee and then to all their legislative representatives.

Assembly Int. No. 996—Mr. Stewart's bill which we mentioned in the bulletin as threatening a powerful influence in the conduct of dispensaries. Note particularly that this bill is not retroactive and, therefore, its conditions will not affect any hospital dispensaries now in existence. There is no doubt but that in certain districts hospital dispensaries are making inroads into the practice of private physicians, but this bill would not correct that situation.

HARRY ARANOW,
JOHN J. BUETTNER,
MARSHALL CLINTON,
Committee on Legislation.

BULLETIN NO. 4

February 17, 1932.

Since our last bulletin the following bills have been introduced:

Senate Int. No. 967—Thompson; Assembly Int. No. 986—Potter, would amend the Mental Hygiene Law by providing hospital unit at Kings Park shall be known as Veterans' Memorial Hospital Division, devoted exclusively to care of war veterans. The object of this bill is to make available to veterans of the Spanish-American war the facilities provided by the Veterans' Memorial Hospital, which was built by the state for the care of veterans of the World War. We understand that this bill was not prepared at the request of the State Department of Mental Hygiene.

Senate Int. No. 994—Wicks; Assembly Int. No. 1098—Austin, to amend the Public Health Law, by providing each board of visitors shall have seven members appointed by Governor for six-year term. This is a measure of the Department of Health providing for the reconstruction of the Board of visitors to the cancer hospital at Buffalo and providing a definite term of office for each visitor.

Senate Int. No. 995—Wicks; Assembly Int. No. 1190—Austin, would amend the Public Health Law relative to the discharge of sewage and other matter into waters of the state in manner injurious to or so as to create a menace to health or a public nuisance, commissioner being empowered to issue permit therefor under certain conditions. This bill was prepared by the Department of Health and has been introduced for several years. It relates particularly to sewage discharged from industrial plants.

Senate Int. No. 1052—Thompson; Assembly Int. No. 1137—Potter, would amend the Mental Hygiene Law to permit use for civilian patients of acute medical and surgical building in hospital unit at Kings Park if commissioner thinks care of veteran soldiers and sailors treated there will be promoted. This is a bill prepared by the State Department of Mental Hygiene, and we believe has the approval of the American Legion, to give the hospital authorities permission to use a certain group of buildings of this Memorial Hospital which have not been in use as yet because their facilities are not needed by the veterans. There is, on the other hand, a civilian need for their use.

Assembly Int. No. 1097—Austin; to amend the Public Health Law by empowering the Public Health Council to prescribe regulations and qualifications of professional and technical positions in state and local health service and to classify such positions. This bill is drawn up in accordance with the recommendations of the Governor's Special Health Commission. It was a part of one of the bills introduced last year and provides particularly that the Public Health Council shall

establish qualifications for pathologists who may be employed in public health laboratories and persons employed at water purifying plants.

Assembly Int. No. 1165—Mr. Cu villier reintroduces his bill of the last several years, authorizing the Department of Health to establish cancer clinics and appropriates \$5,000,000.

Assembly Int. No. 1167—Mr. Cu villier reintroduces his health insurance bill, the omnibus bill which we have seen annually for quite a number of years.

Assembly Int. No. 1191—Mr. Bernhardt introduces the anti-vivisection bill which is already sponsored by Mr. Vaughan. Mr. Vaughan's bill had a hearing before the Codes Committee. Some of the proponents of the bill have concluded that they have made a mistake in having their bill sponsored by a democrat and so have persuaded Mr. Bernhardt, a republican, to sponsor it. There is a rumor that the Anti-Vivisection Society is about to split over this matter. Several ladies who assisted Mrs. Belais in promoting the cause, have of their own initiative secured Mr. Bernhardt's assistance.

There is great necessity for developing a more lively interest among lay persons in support of the position taken by the doctors on this bill. The Anti-Vivisection Society has been campaigning against certain assemblymen and in some districts the number of names on their petitions is greater than the majority by which the assemblymen have been elected. Annually, these men who are staunch supporters of ours, wonder whether the persons who sign those petitions might not vote against them. We hope that every chairman will do his utmost to counteract the influence of the Anti-Vivisection Society's political aspirations and remember that the local humane society is generally an exponent of the Anti-Vivisection Society.

ACTION ON BILLS

The Westall-Gamble Bill—Senate Int. No. 256; Assembly Int. No. 473—which provides that county boards of health shall have three physicians instead of two, has passed the Senate and reached third reading in the Assembly.

Senate Int. No. 634—Wicks; Assembly Int. No. 794—Austin—has been reported out in the Senate and reached third reading in the Assembly.

Senate Int. No. 636—Wicks; Assembly Int. No. 792—Austin—has been reported out in the Senate and reached third reading in the Assembly.

Senate Int. No. 635—Wicks; Assembly Int. No. 793—Austin—has been reported out in the Senate.

Senate Int. No. 11—Mr. Love's "baby mixing" bill was reported out on Monday for consideration. It produced a great deal of discussion, mostly humorous, and finally was recommitted.

* * *

For some unaccountable reason, there was a delay in having the white books printed. They

are at last available and a copy is enclosed for those who have not already received one with bills which went out yesterday.

HARRY ARANOW,
JOHN J. BUETTNER,
MARSHALL CLINTON,
Committee on Legislation.

COMMITTEE ON PUBLIC RELATIONS

The Public Relations Committee which had been engaged jointly with the Public Health Committee in the study of the report of the Governor's Health Commission up to January first, during the latter half of the year 1931, held its first meeting in New York on January twenty-seventh and considered the following agenda:

I. Medical problems of workmen's compensation administration.

II. Conference with the Division of Physical Education in the Department of Education regarding examination of school children.

III. Friendly visits with chairmen of half a dozen county committees at one time for purpose of ascertaining their potential possibilities for work and outlining program.

IV. Preparation of historical sketches for publication in the *NEW YORK STATE JOURNAL OF MEDICINE*, and such newspapers as will carry them. The following subjects were considered:

Development of hospitals.

Extent of the education of students in medicine.

Saving babies' lives.

Calling the doctor in 1832 and 1932.

Disappearance of malaria, typhoid and diphtheria.

Items number II and III were adopted for immediate follow-up.

The Department of Education is administering the school health examination law. Every school child should be examined by the family physician and furnished a certificate. Four things should be accomplished:

1. Exclusion of children having communicable diseases.

2. The use of all the accepted immunizations.

3. The correction of all remediable defects.

4. Good records, kept up to date from year to year and made in duplicate—one for the school and one for the family doctor, because he is the most valuable agent for the correction of defects. An especial effort should be made to stimulate the interest of the physician in the work of good examinations of school children.

Following the committee meeting there was a conference with Dr. Thomas Parran, State Commissioner of Health, Dr. George W. Kosmak, Chairman of the Maternity Center Association; Dr. Elizabeth M. Gardiner, Director of the Division of Maternity and Child Welfare of the State Department of Health; and Dr. Thomas P. Farmer of the Committee on Public Health and Medical Education, on a proposed outline of steps to be taken to inaugurate a study of maternal mortality. Details were agreed upon in the conference between the medical profession and the State Department of Health with mutual satisfaction and pleasure at the evidence of good will and cooperation. It was felt to be the beginning of a new era of cooperation in all matters of public health.

The first sectional meeting of the Public Relations Committee with representatives of eight or ten County Societies will be held in Albany on the afternoon of February eighteenth. The purpose of the sectional meeting is to advance knowledge of the increasing value of medical leadership in cooperative health effort both in the interest of public health and in professional economic welfare.

JAMES E. SADLIER, *Chairman.*
W. H. ROSS, *Secretary.*

KINGS COUNTY

The scientific program of the stated meeting of the Medical Society of the County of Kings, held on Tuesday, January 19, 1932, was as follows:

1. Inaugural Address: "Medicine Besieged," Dr. William Linder, M.D., F.A.C.S., President, Medical Society of the County of Kings.

2. Address: "Concerning the Pedigree of Man," William King Gregory, A.B., A.M., Ph.D., Professor of Vertebrate Palaeontology, Columbia University.

Dr. Linder discussed the problem of medical costs and the need for remedial legislation to correct current abuses. He emphasized the necessity of every physician being a member of his County and State Society, so that the necessary reforms could come about through internal rather than external control. "It is my sincere hope we will all interest ourselves in the problem of economic medicine so that we will be prepared to follow and support a great medical statesman who may, in the near future, be found among us to point the way."

On Saturday, January 23rd, 1932, the Jewish Hospital of Brooklyn, at its annual dinner and ball, held in the Waldorf-Astoria in New York, did honor to Dr. William Linder, the chief surgeon of the medical staff, to celebrate his election to the presidency of the Medical Society of the County of Kings.

In the course of the celebration, Dr. Linder was presented with a set of books, with the understanding that these books be turned over, at once, to the Library of the County Society, as a me-

mento of the occasion. The set was the sixth edition, in six volumes, of *Handbuch der Practischen Chirurgie*, originally edited by E. von Bergmann, P. von Bruns and J. von Mikulicz, revised and edited by C. Garre, H. Küttner and E. Lexer. These volumes are already available for reference to the Medical Society.

We are pleased to announce the resumption of the Friday Afternoon Practical Lectures, which are held in the County Society Building, 1313 Bedford Avenue, Brooklyn, at five o'clock. The spring series for 1932 is as follows:

- March 4th—"Pathology of the Heart," Harrison S. Martland, M.D., Newark, N. J.
- March 11th—"Differential Diagnosis of Acute Abdominal Conditions," Samuel A. Loewenberg, M.D., Philadelphia, Pa.
- March 18th—"More Common Diseases of the Teeth and Jaws," Theodor Blum, D.D.S., M.D., Manhattan.
- March 25th—(No lecture—Good Friday.)
- April 1st—"Cancer of the Stomach," I. Harris Levy, M.D., Syracuse, N. Y.
- April 8th—"Common External Diseases of the Eye and Their Treatment," Bernard Samuels, M.D., Manhattan.
- April 15th—"Osteomyelitis," Dean Lewis, M.D., Baltimore, Md.
- April 22nd—"The Treatment of Circulatory Failure," Ernst P. Boas, M.D., Manhattan.
- April 29th—(Lecture to be announced.)
- May 6th—"Neurological Diagnosis in General Medicine," Israel Strauss, M.D., Manhattan.
- May 13th—"Diagnosis and Management of Uterine Bleeding," Louis E. Phaneuf, M.D., Boston, Mass.

RENSSELAER COUNTY

The regular monthly meeting of the Medical Society of the County of Rensselaer was held in the health center on Tuesday, February 9, 1932.

Dr. Hambrook reported for the legislative committee. Drs. A. J. Hambrook, Wm. B. D. Van Auken, and Warren St. John were appointed as a committee to study and make suitable changes for revision of the Constitution and By-laws.

Mr. Verne A. Zimmer, Director of Compensation of the State Department of Labor, addressed the society stating that under the compensation laws doctors were called upon to prognosticate more accurately than ever before. He stressed the value of thoroughness in physical diagnoses and in the keeping of records as well as promptness with reports.

Dr. Charles F. Goodrich of Brooklyn, N. Y., chairman of the committee on Medical Economics of the State Medical Society, addressed the so-

cietiy on "The Reformation of Medical Economics with Special Consideration of the Arbitration Agreement."

He spoke in detail of the operation of the compensation act with special reference to the County society's economics committee and the function of the arbitration board. He stated that he believed that ninety per cent of the profession was being cursed and damned for the sins of the other ten per cent, and that our profession would have to cleanse itself from within.

The third speaker of the evening, Attorney John J. Scully of Albany, gave a good address on insurance from the viewpoint of the carrier. The title of his address was "A Proposed Fee Schedule."

The meeting adjourned at 11:30 p.m. and refreshments and a social hour followed.

W. B. VAN AUKEN, *Reporter*.

ONONDAGA COUNTY

As a result of a questionnaire sent to the members of the Onondaga Medical Society early in 1931, this Society requested from the Committee on Public Health and Medical Education of the Medical Society of the State of New York a program of lectures dealing with different phases of physical therapy.

The following program was provided by this Committee:

Jan 7th—Application of High Frequency Currents, Diathermy and Electrosurgery Richard Kovacs, M.D., New York.

Jan 14th—Physical Therapy without Apparatus G. K. Hansson, M.D. New York.

Jan 28th—Physical Therapy in Fractures and Other Traumatic Conditions C. R. Murry, M.D., New York.

Feb 4th—Physical Therapy in Arthritis and Rheumatoid Conditions William Bierman, M.D., New York.

The lectures were delivered at 4:30 P.M. in the auditorium of St. Joseph Hospital, two of them being preceded by a short practical demonstration of the subject matter discussed. The lectures were essentially practical in nature and proved to be of considerable interest to those attending.

Advance publicity was freely employed in connection with the Academy of Medicine and County Society programs and announcements. In addition to this a reminder card calling attention to the subject, speaker, time and place was mailed to each member by the County Secretary, Dr. E. E. Mack, two days before the lecture. The attendance was satisfactory.

In addition to these lectures a series of eight

practical demonstrations were held in the physical therapy departments of local institutions where different phases of the subject were presented.

Dr. J. J. Levy, Syracuse University Hospital

1—Air-Cooled Ultraviolet

2—Massage

3—Passive Manipulation

Dr. T. C. Walsh, St. Joseph Hospital

1—High Frequency Electrotherapy

2—Low Tension Electrotherapy

3—Neuromuscular Electrodagnosis

Dr. C. P. Hutchins, The Aetna Life Insurance Clinic

1—Water Cooled Ultraviolet

2—Curative Work Shop

3—Physical Therapy on a Pathological Basis

Dr. L. A. Hadley, Syracuse Memorial Hospital

1—Hydrotherapy

2—Electrocoagulation

3—Therapeutic Pyrexia

Members of the Society who registered for this seminar were divided into four groups and spent about one hour on two different mornings in each of the cooperating institutions. The teaching of technique to registrants was not emphasized. Particular attention was given to indications, contra indications, prescribing of the treatments on the basis of pathology, and other general considerations.

Attendance and interest at these demonstrations was very satisfactory and the feeling was general that the seminar had been well worth while.

LEE A. HADLEY,
*Chairman County Committee on
Physical Therapy*

HERKIMER COUNTY

A regular meeting of the Herkimer County Medical Society was held in Herkimer on February 9, 1932, with twenty-three members present.

The proceedings were in honor of Dr. William D. Garlock of Little Falls, on his completing fifty years of practice. Papers carefully prepared on the life and times of Dr. Garlock were read by Drs. Harry W. Vickers and George S. Eveleth, of Little Falls, and Dr. Garlock responded with reminiscences of his medical career.

Dr. Garlock was born on April 2, 1855, in

Garlock's Corners, almost in sight of the city where he has practiced medicine for a half century. He was president of the Herkimer County Medical Society in 1890, and the Fifth District Branch in 1902.

Dr. Garlock has a store of knowledge of other subjects besides medicine. He has a telescope and uses it in studying the heavens. He is also an authority on geology, recording and publishing his observations and securing the recognition of the geological experts.

THE DAILY PRESS

RELIEF OR DOLE

Legislators and administrators from township trustees to United States senators are divided into two schools of thought as they wrestle with the problems created by the world-wide financial depression. The two schools are alike in proposing gifts of money either directly, or indirectly; but they differ in regard to the name of the donation—one calling it an honorable relief fund, and the other, a dole. The arguments of the two schools are illustrated by a description of a two-hour debate in the United States Senate reported in the *New York Herald Tribune* of February eleventh. The bill appropriating \$375,000,000 was under debate, and the following dialogue occurred:

Speaker No. 1: "That is the opening wedge to the dole."

Speaker No. 2: "A government which will not protect those who protect it is flying a flag which is a dirty rag, contaminating the air in which it flies."

Speaker No. 1: "If we leave this relief problem in the hands of the politicians, God help America."

Speaker No. 2: "We are simply undertaking to control a crisis. Thousands are unable to take care of themselves. There is not a semblance of a dole here. If this is a dole, then Illinois, Pennsylvania and other states are paying a dole. I am convinced there is widespread and terrible suffering in this country. Thousands and millions of homes have not had a day free from care in eighteen months. Disease has visited homes and is taking the children. I sometimes doubt if the great war itself entailed greater misery, more agony of heart and mind than this crisis. True

the armies left their dead and dying, but who cannot paint a picture of desolation and ruin and blasted hopes behind this army of unemployed."

Speaker No. 1: "I am opposed to the Federal government entering on this relief program because when it does there will be no end. It will be progressive. It is not the length of the first step that is dangerous. It is the direction. There is not a city in the country that can't take care of its unemployed."

Speaker No. 2: "Suppose the local community had carried on its relief work for two years and its means of continuing were exhausted."

Speaker No. 1: "I would send some one like the Senator from ——— to investigate."

Speaker No. 2: "Meanwhile babies would die and mothers would starve."

Speaker No. 1: "And that in a civilized community?"

Speaker No. 2: "I am not sure about civilization since I heard the Senator."

Speaker No. 1: "It is not in the general welfare to destroy every fiber of American government by this proposition of giving money away."

Speaker No. 2: "Men who voted to take money out of the Treasury to revive business are now unwilling to take money to save human lives. The issue is materialism against humanity."

Speaker No. 1: "You propose to have the government support the people, instead of the people the government."

Speaker No. 2: "The theory that the people support the government passed away with the revolution."

In the meantime physicians are giving relief to the sick without words or other fuss.

MONDAY SICKNESS IN LONDON

London doctors seem to consider Monday to be their busy day, although this is probably not true in America. The *New York Times* of January 22 makes the following comment on "Monday, the Doctors' Day":

"To many physicians in London the Monday after Christmas brought a rush of patients. Many had barely time 'to pause for a cup of tea.' The celebrations and feasting for Christmas and Boxing Day were doubtless responsible.

"But Monday is regularly a busy day for doctors, they told an inquiring reporter. Week-end parties are often responsible for late hours and over-indulgence in eating and drinking, with their

attendant ailments. For reluctant schoolboys a Monday illness, real or imaginary, means an added day of freedom. For people who contemplate consulting a doctor, there seems to be an 'unaccountable psychological urge' to make the appointment for Monday—perhaps because Monday is proverbially 'blue.'

"London's after-Christmas ills last year were not largely due to over-eating. A suggested explanation was that the keen public interest in diet caused a curtailing of Christmas menus. It is possible that business conditions may have had something to do with the decline in holiday gormandizing."

ACQUIRING HEALTH

A favorite argument put forth by educators to inspire the children of the land to take exercise is that certain men, sickly in their childhood, have achieved the front pages of our daily newspapers

because of their vigor induced by their attention to diet and exercise. James J. Montague, writing in the *New York Herald Tribune* of February 10, reports his experience as follows

WORSF THAN THE DISEASE

"From my youth I have envied the people
Who suffer no physical ills,
Who, through year after year, are immune to the fear
Of druggists' and specialists' bills
I was born with a frail constitution,
Yet I managed to muddle along
Till I made up my mind that I'd go forth and find
The means to grow healthy and strong

"So I studied the subject of diet,
Ate only prescribed kinds of food
Till I learned the right fare, after which I took care
That each bite should be thoroughly chewed
But still I was nervous and feeble
And often confined to my bed
With shuddery quakes and with brain-racking aches,
Which threatened to wrench off my head

"So I took up gymnastics and boxing,
Ran a mile before breakfast each day,
I golfed and I bowled till I caught a bad cold,
Which sapped all my vigor away
Next I put in hard grueling efforts
A heavy canoe to propel,
And my biceps grew strong as I paddled along,
However, I failed to get well

"Today I am shattered and shaky
And barely can walk down the street,
Little food I can touch, and I don't care so much,
For but very few things I can eat
I have long given up all ambition
To gain either wisdom or wealth,
But at last I've found out, past a shadow of doubt,
Getting healthy has ruined my health"

A MODERN BAD BOY

The execution of Francis Crowley, aged 20, for murder was the occasion for the newspapers to discuss the modern bad boy, and the influences which produced him. Physicians will be interested in the following article in the *New York Times* of January 22:

"The life of Francis Crowley epitomized from first to last the career of the petty thug, youthful and ruthless, who has sprung up in our modern cities. Undersized, underchinned, underwitted—he never could learn to read and write in any but the crudest fashion and he never developed beyond the mental age of ten and a half—the world would never have known he existed if he had not turned to crime. And, having vanity, he turned to crime."

Crowley was an illegitimate child who was brought up on a baby farm.

He never could learn at school. He ran away when he could and so gradually fell in with the hoodlum gangs from which he derived the only sense of values he ever knew. He worked at times as a delivery boy and learned to drive automobiles. They fascinated him. One of his favorite crimes in his last two years was stealing them."

He participated in two or three shooting affairs, and acquired the nick name "two gun," and gloried in the prestige which it gave him in dance halls and among thugs.

After being sentenced to death he made one more appearance in public, as he testified in a hold-up case, trying to save the prisoner for his own personal glory.

"Crowley, flanked by prison keepers, came down from the death cell to testify. With nothing to lose he played the part of the bad man to the hilt. He chewed gum, snarled, boasted, twitted and flaunted the attorneys and went back to his death cell with a final "best regards" to the district attorney. The jury did not believe Crowley and O'Brien was convicted again."

A prominent police officer said "He was a fake bad man with the soul of a rat. He fought when he was cornered as a cornered rat will fight. He was dangerous when he got the draw, but he never really shot it out with any one," but this referred to the fully developed mental disorder or defect. The problem from a medical and sociological point of view was the preventive treatment of the boy before his perverted ideas became fixed.

THE DAILY PRESS

RELIEF OR DOLE

Legislators and administrators from township trustees to United States senators are divided into two schools of thought as they wrestle with the problems created by the world-wide financial depression. The two schools are alike in proposing gifts of money either directly, or indirectly; but they differ in regard to the name of the donation—one calling it an honorable relief fund, and the other, a dole. The arguments of the two schools are illustrated by a description of a two-hour debate in the United States Senate reported in the *New York Herald Tribune* of February eleventh. The bill appropriating \$375,000,000 was under debate, and the following dialogue occurred:

Speaker No. 1: "That is the opening wedge to the dole."

Speaker No. 2: "A government which will not protect those who protect it is flying a flag which is a dirty rag, contaminating the air in which it flies."

Speaker No. 1: "If we leave this relief problem in the hands of the politicians, God help America."

Speaker No. 2: "We are simply undertaking to control a crisis. Thousands are unable to take care of themselves. There is not a semblance of a dole here. If this is a dole, then Illinois, Pennsylvania and other states are paying a dole. I am convinced there is widespread and terrible suffering in this country. Thousands and millions of homes have not had a day free from care in eighteen months. Disease has visited homes and is taking the children. I sometimes doubt if the great war itself entailed greater misery, more agony of heart and mind than this crisis. True

the armies left their dead and dying, but who cannot paint a picture of desolation and ruin and blasted hopes behind this army of unemployed."

Speaker No. 1: "I am opposed to the Federal government entering on this relief program because when it does there will be no end. It will be progressive. It is not the length of the first step that is dangerous. It is the direction. There is not a city in the country that can't take care of its unemployed."

Speaker No. 2: "Suppose the local community had carried on its relief work for two years and its means of continuing were exhausted."

Speaker No. 1: "I would send some one like the Senator from ——— to investigate."

Speaker No. 2: "Meanwhile babies would die and mothers would starve."

Speaker No. 1: "And that in a civilized community?"

Speaker No. 2: "I am not sure about civilization since I heard the Senator."

Speaker No. 1: "It is not in the general welfare to destroy every fiber of American government by this proposition of giving money away."

Speaker No. 2: "Men who voted to take money out of the Treasury to revive business are now unwilling to take money to save human lives. The issue is materialism against humanity."

Speaker No. 1: "You propose to have the government support the people, instead of the people the government."

Speaker No. 2: "The theory that the people support the government passed away with the revolution."

In the meantime physicians are giving relief to the sick without words or other fuss.

MONDAY SICKNESS IN LONDON

London doctors seem to consider Monday to be their busy day, although this is probably not true in America. The *New York Times* of January 22 makes the following comment on "Monday, the Doctors' Day":

"To many physicians in London the Monday after Christmas brought a rush of patients. Many had barely time 'to pause for a cup of tea.' The celebrations and feasting for Christmas and Boxing Day were doubtless responsible.

"But Monday is regularly a busy day for doctors, they told an inquiring reporter. Week-end parties are often responsible for late hours and over-indulgence in eating and drinking, with their

attendant ailments. For reluctant schoolboys a Monday illness, real or imaginary, means an added day of freedom. For people who contemplate consulting a doctor, there seems to be an 'unaccountable psychological urge' to make the appointment for Monday—perhaps because Monday is proverbially 'blue.'

"London's after-Christmas ills last year were not largely due to over-eating. A suggested explanation was that the keen public interest in diet caused a curtailment of Christmas menus. It is possible that business conditions may have had something to do with the decline in holiday gourmandizing."

ASTHMA AND HAY FEVER IN THEORY AND PRACTICE
By ARTHUR F. COCA, M.D. MATTHEW WALZER, M.D.,
and AUGUST A. THOMMEN, M.D. Quarto of 851 pages,
illustrated Springfield Charles C. Thomas, 1931
Cloth, \$8.50

This volume presents one of the most comprehensive and exhaustive treatments of its subject yet published. Although arranged in three parts each of which has been written by a different author the work is well joined, and demonstrates few of the discrepancies and contradictions so often found where the responsibilities of authorship are divided.

Part I, by Coca, deals with the theoretical and many of the practical aspects of human and animal hypersensitivity. These two conditions better known as allergy and anaphylaxis are compared and contrasted. A critical review is presented of the outstanding experimental studies that have influenced the development of our idea of hypersensitivity. The hypersensitivity of infection of the tuberculin type has been considered in a separate chapter. Of considerable practical importance is the chapter devoted to a description of the preparation of extracts and solutions for use in the testing and treatment of human hypersensitivity.

Part II, upon asthma by Walzer has as its two most outstanding features its chapter upon the Pathology of Bronchial Asthma and its chapter by Bowman and Walzer, upon Atopics and Other Excitants. In the former chapter, there have been collected the autopsy findings in detail upon 33 cases of asthma with clinical data representing all the more complete reports to be found in the literature. In the latter chapter there is a most comprehensive study of the various excitants of asthma (inhalants, 'ingestants', contactants) with a description of their varied and numerous uses in the arts and trades in food and drugs. This chapter will be welcomed by all workers in allergy.

Part III, by Thommen upon Hay Fever contains a remarkably complete section upon the botanical considerations of the plants causing and suspected of causing hay fever. There are many drawings and photomicrographs of pollens and plant structures. An important chapter upon surveys of the hay fever flora of different sections is most instructive. An absorbing chapter upon the history of hay fever is given.

Upon first contact with this volume one is impressed and somewhat bewildered by the wealth of information gathered therein and although there is a degree of justice in the criticism that the volume is somewhat unwieldy yet the authors are certainly to be congratulated upon doing what they set out to do—to create a work that would be a necessity to every worker in the field of clinical hypersensitivity. WILI C. SPAIN

COLLECTED PAPERS 1904-1929 By EDWIN BEHR, M.D.
Octavo of 827 pages illustrated. New York Paul B. Hoeber Inc. 1931. Cloth \$7.50

Eighty nine articles written by the author and embracing practically every branch of surgical endeavor have been collected into one volume of 800 pages.

This book therefore does not only furnish a great mass of detailed information on various subjects gathered by one man in his vast experience but it also portrays the mental stature of the author so well known to all American surgeons. GEO. WERN

BACKACHE By JAMES M'FARLAND, M.A. M.D. Octavo of 199 pages illustrated. Philadelphia P. Blakiston's Son and Co. Inc. 1931. Cloth \$3.00

The monograph is over two thirds devoted to history taking and examination. These two subjects are complete and well arranged. It is very fully illustrated with diagrams.

In this monograph pathological consideration of the disease entities are only lightly touched upon and are for

the most part inadequate. In regards to treatment the author is very incomplete and over emphasizes manipulative procedure which in some instances anatomically cannot produce motion or correction of the affected joints. K. T. YOUNG

MEDICAL JURISPRUDENCE By ALFRED W. HERZOG, Ph.D., A.M. Quarto of 1051 pages. Indianapolis, The Bobbs-Merrill Company, 1931. Cloth \$15.00

This work when viewed from its legal aspect shows an immense amount of work in compiling the cases and decisions under the different headings.

The medical aspect of the work is certainly very weak especially the sections devoted to neurology and psychiatry. ARTHUR C. BRUSH

TEXT-BOOK OF PHYSICAL THERAPY By WILLIAM BEN HART SNOW, M.D. Volume I. Octavo of 708 pages illustrated. New York Scientific Authors' Publishing Company 1931. Cloth \$10.00

It is with a feeling of appreciation and reverence that the reviewer approached this volume. In the recent death of the author physical therapy has lost its greatest exponent and father. It is rather fortunate for medicine that the volume should have been completed before his untimely demise. From our knowledge of the author this book is really an autobiography of Dr. Snow's life and teachings.

It is impossible for one to discuss or summarize all of the topics in this volume because it covers the entire field of medicine still each phase is so important that one does not know what to eliminate. It is only possible to give a general impression of the highly important work. It is a well written and highly interesting volume covering all phases of physical therapeutics. The armamentarium of physical therapy is thoroughly discussed. Also the various modalities as produced by every form of apparatus. Their action, indication, dosage or modes of administration. The applications of their various forms of therapy are properly illustrated with case reports.

The only criticism that can be directed towards this work is the lack of the author's appreciation regarding periodicity of disease. A good deal of credit is taken to the form of therapy applied and too little given to the natural reactions that occur during the course of many diseases mentioned. But this criticism also applies to the enthusiast in other forms of therapy.

In short this volume can be classed as a system of medicine with special regard to therapy. B. KOVEN

INTERNATIONAL CLINICS Edited by HENRY W. CATTALL, A.M. M.D. Forty first Series. Volume III. Octavo of 326 pages illustrated. Philadelphia and London J. B. Lippincott Company 1931. Cloth \$3.00

There are many excellent articles in this volume which in part is devoted to honoring one of the nation's ablest clinical lecturers—Lowell Franklin Barker—on the occasion of his sixty fourth birthday. A foreword is written by W. S. Thayer and an appreciation is presented by Fielding H. Garrison. Clinical lectures are given by Barker at the Harvard Medical Society and ward rounds in the Peter Bent Brigham Hospital are made by him illustrating the methods of procedure in diagnosis.

In addition able clinical papers are presented on the heart and abnormalities of the blood. Abnormal conditions in the lungs are presented especially one on chronic non-tuberculous basic disease of the lungs. There are valuable papers on conditions in the central nervous system. This volume contains much valuable information and upholds the excellence of the other volumes of these clinics. HENRY MORRIS MOSES

BOOK REVIEWS

GONORRHEA IN THE MALE AND FEMALE. A Book for Practitioners. By P. S. PELOUZE, M.D. Second edition. Octavo of 440 pages, illustrated. Philadelphia and London, W. B. Saunders Company, 1931. Cloth, \$5.50.

The second edition includes new chapters on gonorrheal arthritis and ophthalmia, and a new part on gonorrhea in the female. In all these the author is leaning on others and merely adds his criticism condemning in the main the too strenuous methods of therapy in vogue.

The other parts taken over from the first edition are as splendid as ever; even in rereading they are enjoyable and stimulating. This seems to be the only book on gonorrhea which is not written like a cookbook and which is in the best sense iconoclastic. It might be well to point out again that the author's concept of gonorrhea rests entirely on the theory of tissue response. At the present time this seems to be not only the most logical viewpoint, but it also helps a great deal in clarifying an otherwise often baffling clinical picture.

H. L. WEHRBEIN.

THE PRACTICE OF MEDICINE. By A. A. STEVENS, A.M., M.D., Third edition. Octavo of 1150 pages, illustrated. Philadelphia and London, W. B. Saunders Company, 1931. Cloth, \$8.00.

The appearance of this book in its third edition, entirely revised, and considered among the best additions to medical literature, in the last decade, is now ready for the student and practitioner, with all the important controversies in general medicine condensed and deleted of any speculative theories.

Thirty-five sections are entirely rewritten. Particularly interesting are the references made for the first time, and all in one volume of the following conditions: Psittacosis, toxoid prophylaxis of diphtheria, immunization to scarlet fever, immunization to measles, antitoxin treatment of erysipelas, acute polynuronitis, vaccinal encephalitis, chronic duodenal stasis and obstruction, massive collapse of lung, hypoglycemia of endogenous origin, hyperparathyroidism, hypoparathyroidism, lipoid-cell splenomegaly of Niemann-Pick, spontaneous subarachnoid hemorrhage, family and hereditary atrophy of optic nerve. Post vaccinal encephalitis, several cases of which have been reported in this country, is now being investigated by the Public Health Service of the United States Government. Immunization to measles and infantile paralysis with whole blood from parents is discussed. The bronchoscopic treatment of massive collapse of lung conditions and all other interesting topics with the latest therapeutic applications are presented in a comprehensive way and should prove of inestimable value to every physician.

The text-book compares favorably with the time honored Osler's "Principles and Practice of Medicine," and Dr. Stevens has carried on where his master left off.

The publishers are to be commended for the excellent way in which the book is presented. The type of paper and print makes it easily read.

In conclusion, one can only use superlatives in reviewing this book.

M. J. DATTELBAUM.

AIDS TO MEDICAL TREATMENT. By J. T. LEWIS, M.D., B.Sc., and T. H. CROZIER, M.D., D.P.H. 16mo of 244

pages. New York, William Wood and Company, 1931. Cloth, \$1.50. (Students Aids Series.)

This is a small book presenting the principal methods of treatment in a very concise form intended principally for medical students approaching their final examination. For a book so small it contains a good deal of information which is well presented.

W. E. MCCOLLUM.

THE DIAGNOSIS AND TREATMENT OF VENEREAL DISEASES IN GENERAL PRACTICE: The Routine Management of Syphilis and Gonorrhoea Employed in the St. Thomas' Hospital Venereal Diseases Department. By L. W. HARRISON, D.S.O., M.B. Fourth edition. Octavo of 567 pages, illustrated. New York, Oxford University Press, 1931. Cloth, 25/. (Oxford Medical Publications.)

This, the fourth edition, contains much new matter, particularly along the lines of treatment and contains over 500 pages of text.

The style of the work has special appeal for the clinician, in that the various cutaneous lesions, also the deeper lesions and visceral changes are grouped by regions, including the complete differential diagnosis in each instance. This method should simplify the problem of a given case for the practitioner. The author emphasizes that no physician is equipped for the proper diagnosis of a primary lesion of lues without a dark-field microscope.

All regions of the body are considered, each in turn, in a given chapter both for gonorrhoea and syphilis and their differential diagnosis. A brief chapter is devoted to venereal diseases in women, and one in children. There is much valuable information to be gained from the chapter on collection and preparation of specimens for diagnosis. A chapter concerning the interpretation of laboratory reports is also useful and helpful.

All the up-to-date accepted modes of therapy are presented. An informative and lengthy chapter on the medico-legal relations of venereal diseases is appended by Dr. F. G. Crookshank. This contains valuable information for those handling venereal problems.

While the work is an excellent guide for physicians concerned in the diagnosis and treatment of venereal disease, it is the humble opinion of the reviewer that no practitioner should undertake treatment of cases, without at least having had a practical working-knowledge of the many problems, gained only by actual experience in venereal disease clinics.

AUGUSTUS HARRIS.

DYNAMIC RETINOSCOPY. By MARGARET DOBSON. Octavo of 56 pages, illustrated. New York, Oxford University Press, 1931. Cloth, \$2.50. (Oxford Medical Publications.)

This is a pithy little brochure of 44 pages. It collects the essentials of the subject and presents them in a clear and concise manner. One is struck by the interrelation which this branch of examination has with other forms of study. There is no doubt that as an objective method of examination dynamic retinoscopy should have a place in the routine of every ophthalmologist. It is capable of disclosing evidence under certain circumstances which prevents the use of subjective methods. For instance the author points out that dynamic retinoscopy is the only objective method of measuring presbyopia.

The work is well worth while.

JOHN N. EVANS.

ASTHMA AND HAY FEVER IN THEORY AND PRACTICE By ARTHUR I. COCA, M.D. MATTHEW WALZER, M.D., and AUGUST A. THOMMEN, M.D. Quarto of 851 pages illustrated Springfield Charles C. Thomas, 1931 Cloth \$8.50

This volume presents one of the most comprehensive and exhaustive treatments of its subject yet published. OUR NEIGHBORS

THE MICHIGAN JOURNAL

The minutes of the meeting of the Council of the Michigan State Medical Society held on January 8, the Secretary, Dr. F. C. Warnshuis, discusses the Journal as follows:

"Last year I estimated advertising revenue of \$8,500—our revenue was \$8,849.23. An estimate of \$8,000 for 1932 is conservative. Our Journal Cost was estimated at \$11,500 and was \$10,187.52. In estimating \$10,000 for 1932, I have not taken in consideration a printing saving of some \$500 to \$600 that will accrue from reduced contract price.

"The business affairs of the Journal are in a satisfactory condition. An advertising income of \$8,849.23 for the year exceeded our expectations when so many business firms have been curtailing advertising expenditures. One is, however, unable to foretell what our experiences will be this coming year. Our contacts cause us to believe that if present financial conditions continue we will encounter at least a 33 1-3 per cent decrease in advertising income. The cancellation of several contracts during the past sixty days is indicative of added curtailment on the part of advertisers.

"An increased advertising income of at least \$5,000 is obtainable if the Council and all our members would but subscribe cooperative support by patronizing our Journal advertisers. Firms advertise for the purpose of securing business, as well as to impart information pertaining to their products. They do not purchase space solely to make a contribution to our publication. Many of the advertisements contain coupons and others contain offers of samples, and literature Contracts are continued when business returns are received. When such returns are not received, contracts are cancelled. If our members would peruse the advertising pages of each issue and spend a few cents for postage, each month, to reply to advertisers, satisfactory proof of the advertising medium value of the Journal would be established and enlarged revenue would accrue. While not urging a boycott, it is recommended that, other things being equal, members limit their business to our advertisers. There are several Michigan firms who are valued patrons of the Journal. Give them preference in placing orders. Tell the salesman who calls on you that you are placing your business with Journal advertisers. If this cooperation and response is exhibited, our advertising income will be maintained and increased.

"Our business relationships with the Bruce Publishing Company have been exceedingly pleas-

ant and satisfactory. Their typographical work is beyond criticism. The fullest degree of cooperation is constantly evidenced. Expressive of their interest and integrity, the President voluntarily advised your Secretary that the printing cost would be reduced thirty-five cents a page during 1932 and if further cost reductions were attainable a still greater reimbursement would be made. This gratifying proposal will produce a printing expense reduction for the year of from \$500 to \$600.

"An added Journal cost has been encountered in the increased number of changes in addresses involving the making of new addressograph plates.

"No charge has been made against the Journal account for correspondence and postage expense incurred in the Secretary's office in discharging the work entailed in the business management of the Journal."

The secretary makes the following recommendations:

"That book reviews in the Journal be limited to publishers who advertise in the Journal. At present publishers receive valuable space at an annual expense to the Journal of approximately \$200 to \$250 per year. Were this space paid for at advertising rates, the annual income would be about \$1,500."

The NEW YORK STATE JOURNAL OF MEDICINE conducts its book reviews as items of scientific information, totally divorced from every business consideration. Every book is reviewed on its merits only, and is condemned if it does not come up to the highest modern standards of practice and literature.

Concerning illustrations in the Journal, the Publication Committee reports:

"The 1931 volume contained 104 half-tone illustrations and 77 line drawings. The cost of these has been borne by the contributors. The editor has drawn attention to instances in which illustrations have consisted of photographs of faces in which there is a possibility of recognizing the subject and suggests that contributors should obtain permission, in writing, to use photographs for illustrations, or to disguise the features so to render identification impossible."

The support given to the editor is mentioned as follows:

"The long experience of the editor has seemed to warrant your Committee in permitting great freedom in the matter of editorial policy. He

(Continued on page 298—Adv. xiv)

ANALGESIC and ANTIPYRETIC ACTION of the CHEMICAL TOLYSIN

AN IMPORTANT COMPARISON

The tables below present important comparisons. These comparisons mark the differences between the salicylates and the chemical, Tolysin, and indicate the superiority of the latter as an analgesic and antipyretic.

THE SALICYLATES (U. S. P.)

Analgesic and Antipyretic,

A distinctive and unpleasant taste,

Cause of nausea and gastro intestinal irritation,

Lacking in definite anti-plastic or anti-inflammatory effect,

Produce less favorable analgesic effect upon muscle, tendon, and joint pain,

Therapeutic range, in the case of aspirin at least, is less than that of Tolysin, (aspirin has one-sixth the therapeutic range of Tolysin in dogs)

Frequently the cause of albuminuria,

Lack of strong uric acid eliminating effect.

Summary Effective analgesic and antipyretic action but frequency of nausea, vomiting and other unpleasant by-effects make desirable the use of an improved treatment, especially in children (as for example, Tolysin, which is rarely accompanied by unpleasant by-effects common to the salicylates).

TOLYSIN (The Chemical)

Analgesic and Antipyretic,

Tasteless,

Neutral — Tolysin is the ETHYL ESTER of PARAMETHYL phenylcinchoninic acid, a neutral chemical,

Practically non-irritant — Tolysin rarely produces nausea or vomiting,

Relatively non-toxic with a wide therapeutic range — six times (in dogs) that of aspirin,

Exerts a definite anti-plastic or anti-inflammatory effect,

Semi specific analgesic action upon pain involving the muscles, tendons, joints or their appendages in contrast to the more general analgesic action of the salicylates,

Does not harm the heart or kidneys,

Gives a uric acid eliminating effect

Summary Tolysin is indicated especially in acute rheumatic fever, infectious fevers, colds, and gripe, as an analgesic in chronic arthritis, and for pain and fever in children and old people. Its use provides relief practically without the discomforts and by-effects often traceable to the salicylates

Tolysin is one example of the construction by The Calco Chemical Company of definite chemical compounds which eliminate the disadvantages of older drugs while retaining and adding to their advantages. It is suggested that Tolysin be tentatively prescribed in two or three cases and the improvement in results noted.

in each

24 ounces of bread

1. Vitamin-D is the scarcest of vitamins in ordinary table foods, according to leading nutritional authorities. (Names and references on request.)

2. Sunshine vitamin-D Bond Bread now richly provides this valuable food element in the diet. (Journal American Medical Association, July 4, 1931.)

3. This improved bread is sold at no extra price.

4. There is no change in the taste or the delicious flavor of the bread.

5. Toasting in no way impairs the sunshine vitamin-D content. (Paediatric Research Foundation.)

Be sure your own family gets wholesome Bond Bread regularly, to build and maintain strong bones and sound teeth. For further information, address Dr. J. G. Coffin, Technical Director.

Bond Bakers

GENERAL BAKING COMPANY

420 LEXINGTON AVE., New York, N.Y.

(Continued from page 302—Adv. xviii)

enumerates seven reasons for its opposition to the bill as follows:

"1. The Sheppard-Towner Maternity and Infancy Act, as passed originally and later modified, failed to materially speed up the decline in the maternal mortality rate during the time of its operation, and there has been no increase in mortality from this source since the law was repealed.

"2. The re-enactment of this measure would, in our estimation, add unjustifiably to the burden already borne by federal and state taxpayers. This would seem not to be the time to increase federal expenditures for any but the most necessary purposes, and who is there who can say that this purpose is necessary at this time, particularly in the face of the united if not unanimous opposition of the largest and most influential group of physicians in the world?

"3. If this type of legislation continues to grow in popularity, the time will soon arrive when some of our states will find it exceedingly difficult if not impossible, to match Federal funds.

"4. The measure represents a most insidious but certain approach to state medicine, so-called, of the most reprehensible type, reprehensible in that it invades, indirectly and, in prospect, directly, the practice of medicine in states, counties and municipalities, all under federal direction and control.

"5. The medical profession is opposed to the socialization of medicine rather because of the anticipated ill effects upon the dependent public than upon the welfare of its own members.

"6. The legislation provides very practically for Federal control of a broad scope of activities in the state, at the expense of both state and federal taxpayers.

"(a) A Federal board is created, comprising the Surgeon General of the U. S. P. H. S., as chairman (doubtless designed to relieve the apprehension of those interested in public health matters), the Chief of the Children's Bureau of the Department of Labor, and the Commissioner of Education of the Department of the Interior,—two to one in favor of lay control.

"(b) The board is given the power to 'approve or disapprove of all plans for cooperative work between the United States and the several states under the Act,' which is equivalent to saying that the Board may direct these activities, for all practical purposes.

"(c) The purpose of the measure is declared to be two-fold, first (so placed as good psychology) to enable the Public Health Service, 'under the general supervision of the Board' to 'co-operate with the state agencies of health in the development of local health units or organizations for the prevention of disease and the promotion of health among the rural population'—second, the purpose of 'enabling the Children's Bureau, under the general supervision of the Board (al-

(Continued from page 304—Idv rx)

ways) to cooperate with the state agencies of health promote the health and welfare of mothers and children'

"(d) The element of coercion is carried by the terms of the appropriation. It is provided that no funds appropriated under the Act shall be made available to the states until an equal sum shall have been made available by the state first for the promotion of the first purpose of the bill and, second for the promotion of its second purpose, both of which we have just recited. But that is merely the foundation. Any state desiring to avail itself of the benefits of the appropriation authorized by the measure must secure the approval of its plan for carrying out the purposes of the law, in addition to appropriating one half of the cost of the entire work.

"(e) Apparently the author of the measure has anticipated and disarmed the opposition of such organizations as christian scientists, antivaccinationists and the like by requiring that the plans for the states shall provide that 'no official or agent, or representative of the state in carrying out the provisions of this Act, shall enter any home or take charge of any child over the objection of the parents or either of them'

"(f) The Children's Bureau, it is provided,

shall withhold allowance to states for maternity and child welfare work under this measure, 'upon request of a majority of the Board'

"7 Finally, let it be understood by all who would know, that in opposing the legislation under discussion the medical profession departs not one jot or tittle from its traditional concern for the health of the public'

MEAT INSPECTION IN MISSOURI

The February issue of the Journal of the Missouri State Medical Association discusses editorially the relation of the St. Louis Medical Society to meat inspection, as follows

"It was long known to the members of the St. Louis Medical Society that the City of St. Louis had no effective ordinance for inspecting local packing houses. The Society's committee on health and public instruction viewed the situation and decided to recommend a campaign to establish municipal meat inspection. The committee was composed of Drs. Charles E. Hyndman, Jerome E. Cook and Robert Vinyard and instructed the executive secretary, Mr. Elmer H. Bartelsmeyer, to make an investigation and report the result to the committee. Mr. Bartelsmeyer

THE DAILY PRESS

RELIEF OR DOLE

Legislators and administrators from township trustees to United States senators are divided into two schools of thought as they wrestle with the problems created by the world-wide financial depression. The two schools are alike in proposing gifts of money either directly, or indirectly; but they differ in regard to the name of the donation—one calling it an honorable relief fund, and the other, a dole. The arguments of the two schools are illustrated by a description of a two-hour debate in the United States Senate reported in the *New York Herald Tribune* of February eleventh. The bill appropriating \$375,000,000 was under debate, and the following dialogue occurred:

Speaker No. 1: "That is the opening wedge to the dole."

Speaker No. 2: "A government which will not protect those who protect it is flying a flag which is a dirty rag, contaminating the air in which it flies."

Speaker No. 1: "If we leave this relief problem in the hands of the politicians, God help America."

Speaker No. 2: "We are simply undertaking to control a crisis. Thousands are unable to take care of themselves. There is not a semblance of a dole here. If this is a dole, then Illinois, Pennsylvania and other states are paying a dole. I am convinced there is widespread and terrible suffering in this country. Thousands and millions of homes have not had a day free from care in eighteen months. Disease has visited homes and is taking the children. I sometimes doubt if the great war itself entailed greater misery, more agony of heart and mind than this crisis. True

the armies left their dead and dying, but who cannot paint a picture of desolation and ruin and blasted hopes behind this army of unemployed."

Speaker No. 1: "I am opposed to the Federal government entering on this relief program because when it does there will be no end. It will be progressive. It is not the length of the first step that is dangerous. It is the direction. There is not a city in the country that can't take care of its unemployed."

Speaker No. 2: "Suppose the local community had carried on its relief work for two years and its means of continuing were exhausted."

Speaker No. 1: "I would send some one like the Senator from ——— to investigate."

Speaker No. 2: "Meanwhile babies would die and mothers would starve."

Speaker No. 1: "And that in a civilized community?"

Speaker No. 2: "I am not sure about civilization since I heard the Senator."

Speaker No. 1: "It is not in the general welfare to destroy every fiber of American government by this proposition of giving money away."

Speaker No. 2: "Men who voted to take money out of the Treasury to revive business are now unwilling to take money to save human lives. The issue is materialism against humanity."

Speaker No. 1: "You propose to have the government support the people, instead of the people the government."

Speaker No. 2: "The theory that the people support the government passed away with the revolution."

In the meantime physicians are giving relief to the sick without words or other fuss.

MONDAY SICKNESS IN LONDON

London doctors seem to consider Monday to be their busy day, although this is probably not true in America. The *New York Times* of January 22 makes the following comment on "Monday, the Doctors' Day":

"To many physicians in London the Monday after Christmas brought a rush of patients. Many had barely time 'to pause for a cup of tea.' The celebrations and feasting for Christmas and Boxing Day were doubtless responsible.

"But Monday is regularly a busy day for doctors, they told an inquiring reporter. Week-end parties are often responsible for late hours and over-indulgence in eating and drinking, with their

attendant ailments. For reluctant schoolboys a Monday illness, real or imaginary, means an added day of freedom. For people who contemplate consulting a doctor, there seems to be an 'unaccountable psychological urge' to make the appointment for Monday—perhaps because Monday is proverbially 'blue.'

"London's after-Christmas ills last year were not largely due to over-eating. A suggested explanation was that the keen public interest in diet caused a curtailing of Christmas menus. It is possible that business conditions may have had something to do with the decline in holiday gormandizing."

ACQUIRING HEALTH

A favorite argument put forth by educators to inspire the children of the land to take exercise is that certain men, sickly in their childhood, have achieved the front pages of our daily newspapers

because of their vigor induced by their attention to diet and exercise. James J. Montague, writing in the *New York Herald Tribune* of February 10, reports his experience as follows:

WORSE THAN THE DISEASE

"From my youth I have envied the people
Who suffer no physical ills,
Who, through year after year, are immune to the
fear
Of druggists' and specialists' bills.
I was born with a frail constitution,
Yet I managed to muddle along
Till I made up my mind that I'd go forth and find
The means to grow healthy and strong.

"So I studied the subject of diet;
Ate only prescribed kinds of food,
Till I learned the right fare, after which I took
care
That each bite should be thoroughly chewed.
But still I was nervous and feeble
And often confined to my bed
With shuddery quakes and with brain-racking
aches,
Which threatened to wrench off my head.

"So I took up gymnastics and boxing,
Ran a mile before breakfast each day;
I golfed and I bowled till I caught a bad cold,
Which sapped all my vigor away.
Next I put in hard grueling efforts
A heavy canoe to propel,
And my biceps grew strong as I paddled along;
However, I failed to get well.

"Today I am shattered and shaky
And barely can walk down the street;
Little food I can touch, and I don't care so much,
For but very few things I can eat.
I have long given up all ambition
To gain either wisdom or wealth,
But at last I've found out, past a shadow of
doubt,
Getting healthy has ruined my health."

A MODERN BAD BOY

The execution of Francis Crowley, aged 20, for murder was the occasion for the newspapers to discuss the modern bad boy, and the influences which produced him. Physicians will be interested in the following article in the *New York Times* of January 22:

"The life of Francis Crowley epitomized from first to last the career of the petty thug, youthful and ruthless, who has sprung up in our modern cities. Undersized, underchinned, underwitted—he never could learn to read and write in any but the crudest fashion and he never developed beyond the mental age of ten and a half—the world would never have known he existed if he had not turned to crime. And, having vanity, he turned to crime."

Crowley was an illegitimate child who was brought up on a baby farm.

"He never could learn at school. He ran away when he could and so gradually fell in with the hoodlum gangs from which he derived the only sense of values he ever knew. He worked at times as a delivery boy and learned to drive automobiles. They fascinated him. One of his favorite crimes in his last two years was stealing them."

He participated in two or three shooting affairs, and acquired the nick-name "two gun," and gloried in the prestige which it gave him in dance halls and among thugs.

After being sentenced to death he made one more appearance in public, as he testified in a hold-up case, trying to save the prisoner for his own personal glory:

"Crowley, flanked by prison keepers, came down from the death cell to testify. With nothing to lose he played the part of the bad man to the hilt. He chewed gum, snarled, boasted, twitted and flaunted the attorneys and went back to his death cell with a final "best regards" to the district attorney. The jury did not believe Crowley and O'Brien was convicted again."

A prominent police officer said: "He was a fake bad man with the soul of a rat. He fought when he was cornered as a cornered rat will fight. He was dangerous when he got the draw, but he never really shot it out with any one"; but this referred to the fully developed mental disease or defect. The problem from a medical and sociological point of view was the preventive treatment of the boy before his perverted ideas became fixed.

BOOK REVIEWS

GONORRHEA IN THE MALE AND FEMALE. A Book for Practitioners. By P. S. PELOUZE, M.D. Second edition. Octavo of 440 pages, illustrated. Philadelphia and London, W. B. Saunders Company, 1931. Cloth, \$5.50.

The second edition includes new chapters on gonorrheal arthritis and ophthalmia, and a new part on gonorrhea in the female. In all these the author is leaning on others and merely adds his criticism condemning in the main the too strenuous methods of therapy in vogue.

The other parts taken over from the first edition are as splendid as ever; even in rereading they are enjoyable and stimulating. This seems to be the only book on gonorrhea which is not written like a cookbook and which is in the best sense iconoclastic. It might be well to point out again that the author's concept of gonorrhea rests entirely on the theory of tissue response. At the present time this seems to be not only the most logical viewpoint, but it also helps a great deal in clarifying an otherwise often baffling clinical picture.

H. L. WEHRBEIN.

THE PRACTICE OF MEDICINE. By A. A. STEVENS, A.M., M.D., Third edition. Octavo of 1150 pages, illustrated. Philadelphia and London, W. B. Saunders Company, 1931. Cloth, \$8.00.

The appearance of this book in its third edition, entirely revised, and considered among the best additions to medical literature, in the last decade, is now ready for the student and practitioner, with all the important controversies in general medicine condensed and deleted of any speculative theories.

Thirty-five sections are entirely rewritten. Particularly interesting are the references made for the first time, and all in one volume of the following conditions: Psittacosis, toxoid prophylaxis of diphtheria, immunization to scarlet fever, immunization to measles, antitoxin treatment of erysipelas, acute polynuronitis, vaccinal encephalitis, chronic duodenal stasis and obstruction, massive collapse of lung, hypoglycemia of endogenous origin, hyperparathyroidism, hypoparathyroidism, lipoid-cell splenomegaly of Niemann-Pick, spontaneous subarachnoid hemorrhage, family and hereditary atrophy of optic nerve. Post vaccinal encephalitis, several cases of which have been reported in this country, is now being investigated by the Public Health Service of the United States Government. Immunization to measles and infantile paralysis with whole blood from parents is discussed. The bronchoscopic treatment of massive collapse of lung conditions and all other interesting topics with the latest therapeutic applications are presented in a comprehensive way and should prove of inestimable value to every physician.

The text-book compares favorably with the time honored Osler's "Principles and Practice of Medicine," and Dr. Stevens has carried on where his master left off.

The publishers are to be commended for the excellent way in which the book is presented. The type of paper and print makes it easily read.

In conclusion, one can only use superlatives in reviewing this book.

M. J. DATTELBAUM.

AIDS TO MEDICAL TREATMENT. By J. T. LEWIS, M.D., B.Sc., and T. H. CROZIER, M.D., D.P.H. 16mo of 244

pages. New York, William Wood and Company, 1931. Cloth, \$1.50. (Students Aids Series.)

This is a small book presenting the principal methods of treatment in a very concise form intended principally for medical students approaching their final examination. For a book so small it contains a good deal of information which is well presented.

W. E. MCCOLLOM.

THE DIAGNOSIS AND TREATMENT OF VENEREAL DISEASES IN GENERAL PRACTICE: The Routine Management of Syphilis and Gonorrhœa Employed in the St. Thomas' Hospital Venereal Diseases Department. By L. W. HARRISON, D.S.O., M.B. Fourth edition. Octavo of 567 pages, illustrated. New York, Oxford University Press, 1931. Cloth, 25/. (Oxford Medical Publications.)

This, the fourth edition, contains much new matter, particularly along the lines of treatment and contains over 500 pages of text.

The style of the work has special appeal for the clinician, in that the various cutaneous lesions, also the deeper lesions and visceral changes are grouped by regions, including the complete differential diagnosis in each instance. This method should simplify the problem of a given case for the practitioner. The author emphasizes that no physician is equipped for the proper diagnosis of a primary lesion of lues without a dark-field microscope.

All regions of the body are considered, each in turn, in a given chapter both for gonorrhœa and syphilis and their differential diagnosis. A brief chapter is devoted to venereal diseases in women, and one in children. There is much valuable information to be gained from the chapter on collection and preparation of specimens for diagnosis. A chapter concerning the interpretation of laboratory reports is also useful and helpful.

All the up-to-date accepted modes of therapy are presented. An informative and lengthy chapter on the medico-legal relations of venereal diseases is appended by Dr. F. G. Crookshank. This contains valuable information for those handling venereal problems.

While the work is an excellent guide for physicians concerned in the diagnosis and treatment of venereal disease, it is the humble opinion of the reviewer that no practitioner should undertake treatment of cases, without at least having had a practical working-knowledge of the many problems, gained only by actual experience in venereal disease clinics.

AUGUSTUS HARRIS.

DYNAMIC RETINOSCOPY. By MARGARET DOBSON. Octavo of 56 pages, illustrated. New York, Oxford University Press, 1931. Cloth, \$2.50. (Oxford Medical Publications.)

This is a pithy little brochure of 44 pages. It collects the essentials of the subject and presents them in a clear and concise manner. One is struck by the interrelation which this branch of examination has with other forms of study. There is no doubt that as an objective method of examination dynamic retinoscopy should have a place in the routine of every ophthalmologist. It is capable of disclosing evidence under certain circumstances which prevents the use of subjective methods. For instance the author points out that dynamic retinoscopy is the only objective method of measuring presbyopia.

The work is well worth while.

JOHN N. EVANS.

ASTHMA AND HAY FEVER IN THEORY AND PRACTICE. By ARTHUR F. COCA, M.D., MATTHEW WALZER, M.D., and AUGUST A. THOMMEN, M.D. Quarto of 851 pages, illustrated. Springfield, Charles C. Thomas, 1931. Cloth, \$8.50.

This volume presents one of the most comprehensive and exhaustive treatments of its subject yet published. Although arranged in three parts, each of which has been written by a different author, the work is well joined, and demonstrates few of the discrepancies and contradictions so often found where the responsibilities of authorship are divided.

Part I, by Coca, deals with the theoretical and many of the practical aspects of human and animal hypersensitiveness. These two conditions, better known as allergy and anaphylaxis, are compared and contrasted. A critical review is presented of the outstanding experimental studies that have influenced the development of our idea of hypersensitiveness. The hypersensitiveness of infection of the tuberculin type has been considered in a separate chapter. Of considerable practical importance is the chapter devoted to a description of the preparation of extracts and solutions for use in the testing and treatment of human hypersensitiveness.

Part II, upon asthma, by Walzer, has as its two most outstanding features, its chapter upon the Pathology of Bronchial Asthma and its chapter, by Bowman and Walzer, upon Atopics and Other Excitants. In the former chapter, there have been collected the autopsy findings in detail upon 33 cases of asthma with clinical data, representing all the more complete reports to be found in the literature. In the latter chapter there is a most comprehensive study of the various excitants of asthma (inhalants, "ingestants," "contactants"), with a description of their varied and numerous uses in the arts and trades, in food and drugs. This chapter will be welcomed by all workers in allergy.

Part III, by Thommen, upon Hay Fever, contains a remarkably complete section upon the botanical considerations of the plants causing, and suspected of causing, hay fever. There are many drawings and photomicrographs of pollens and plant structures. An important chapter upon surveys of the hay fever flora of different sections is most instructive. An absorbing chapter upon the history of hay fever is given.

Upon first contact with this volume one is impressed and somewhat bewildered by the wealth of information gathered therein; and although there is a degree of justice in the criticism that the volume is somewhat unwieldy yet the authors are certainly to be congratulated upon doing what they set out to do—to create a work that would be a necessity to every worker in the field of clinical hypersensitiveness. WILL C. SPAIN.

COLLECTED PAPERS, 1904-1929. By EDWIN BEFR, M.D. Octavo of 827 pages, illustrated. New York, Paul B. Hoeber, Inc., 1931. Cloth, \$7.50.

Eighty-nine articles written by the author and embracing practically every branch of surgical endeavor, have been collected into one volume of 800 pages.

This book, therefore, does not only furnish a great mass of detailed information on various subjects gathered by one man in his vast experience, but it also portrays the mental stature of the author, so well known to all American surgeons. GEO. WEBB.

BACKACHE. By JAMES MENNEL, M.A., M.D. Octavo of 199 pages, illustrated. Philadelphia, P. Blakiston's Son and Co., Inc., 1931. Cloth, \$3.00.

The monograph is over two-thirds devoted to history taking and examination. These two subjects are complete and well arranged. It is very fully illustrated with diagrams.

In this monograph pathological consideration of the disease entities are only lightly touched upon and are for

the most part inadequate. In regards to treatment the author is very incomplete and over emphasizes manipulative procedure which in some instances anatomically cannot produce motion or correction of the affected joints. K. T. YOUNG.

MEDICAL JURISPRUDENCE. By ALFRED W. HERZOG, Ph. B., A.M. Quarto of 1051 pages. Indianapolis, The Bobbs-Merrill Company, 1931. Cloth \$15.00.

This work when viewed from its legal aspect shows an immense amount of work in compiling the cases and decisions under the different headings.

The medical aspect of the work is certainly very weak especially the sections devoted to neurology and psychiatry. ARTHUR C. BRUSH.

TEXT-BOOK OF PHYSICAL THERAPY. By WILLIAM BENHAM SNOW, M.D. Volume 1. Octavo of 708 pages, illustrated. New York, Scientific Authors' Publishing Company, 1931. Cloth, \$10.00.

It is with a feeling of appreciation and reverence that the reviewer approached this volume. In the recent death of the author, physical therapy has lost its greatest exponent and father. It is rather fortunate for medicine that the volume should have been completed before his untimely demise. From our knowledge of the author this book is really an autobiography of Dr. Snow's life and teachings.

It is impossible for one to discuss or summarize all of the topics in this volume because it covers the entire field of medicine, still each phase is so important that one does not know what to eliminate. It is only possible to give a general impression of the highly important work. It is a well written and highly interesting volume covering all phases of physical therapeutics. The armamentarium of physical therapy is thoroughly discussed. Also the various modalities as produced by every form of apparatus. Their action, indication dosage or modes of administration. The applications of their various forms of therapy are properly illustrated with case reports.

The only criticism that can be directed towards this work is the lack of the author's appreciation regarding periodicity of disease. A good deal of credit is taken to the form of therapy applied and too little given to the natural reactions that occur during the course of many diseases mentioned. But this criticism also applies to the enthusiast in other forms of therapy.

In short this volume can be classed as a system of medicine with special regard to therapy. B. KOVEN.

INTERNATIONAL CLINICS. Edited by HENRY W. CATTELL, A.M., M.D. Forty-first Series, Volume III. Octavo of 326 pages, illustrated. Philadelphia and London, J. B. Lippincott Company, 1931. Cloth, \$3.00.

There are many excellent articles in this volume which in part is devoted to honoring one of the nation's ablest clinical lecturers—Lewellyn Franklin Barker—on the occasion of his sixty-fourth birthday. A foreword is written by W. S. Thayer and an appreciation is presented by Fielding H. Garrison. Clinical lectures are given by Barker at the Harvard Medical Society and ward rounds in the Peter Bent Brigham Hospital are made by him, illustrating the methods of procedure in diagnosis.

In addition able clinical papers are presented on the heart and abnormalities of the blood. Abnormal conditions in the lungs are presented, especially one on chronic non-tuberculous basic disease of the lungs. There are valuable papers on conditions in the central nervous system. This volume contains much valuable information and upholds the excellence of the other volumes of these clinics. HENRY MONROE MOSES.

OUR NEIGHBORS

THE MICHIGAN JOURNAL

The minutes of the meeting of the Council of the Michigan State Medical Society held on January 8, the Secretary, Dr. F. C. Warnshuis, discusses the Journal as follows:

"Last year I estimated advertising revenue of \$8,500—our revenue was \$8,849.23. An estimate of \$8,000 for 1932 is conservative. Our Journal Cost was estimated at \$11,500 and was \$10,187.52. In estimating \$10,000 for 1932, I have not taken in consideration a printing saving of some \$500 to \$600 that will accrue from reduced contract price.

"The business affairs of the Journal are in a satisfactory condition. An advertising income of \$8,849.23 for the year exceeded our expectations when so many business firms have been curtailing advertising expenditures. One is, however, unable to foretell what our experiences will be this coming year. Our contacts cause us to believe that if present financial conditions continue we will encounter at least a 33 1-3 per cent decrease in advertising income. The cancellation of several contracts during the past sixty days is indicative of added curtailment on the part of advertisers.

"An increased advertising income of at least \$5,000 is obtainable if the Council and all our members would but subscribe cooperative support by patronizing our Journal advertisers. Firms advertise for the purpose of securing business, as well as to impart information pertaining to their products. They do not purchase space solely to make a contribution to our publication. Many of the advertisements contain coupons and others contain offers of samples, and literature Contracts are continued when business returns are received. When such returns are not received, contracts are cancelled. If our members would peruse the advertising pages of each issue and spend a few cents for postage, each month, to reply to advertisers, satisfactory proof of the advertising medium value of the Journal would be established and enlarged revenue would accrue. While not urging a boycott, it is recommended that, other things being equal, members limit their business to our advertisers. There are several Michigan firms who are valued patrons of the Journal. Give them preference in placing orders. Tell the salesman who calls on you that you are placing your business with Journal advertisers. If this cooperation and response is exhibited, our advertising income will be maintained and increased.

"Our business relationships with the Bruce Publishing Company have been exceedingly pleas-

ant and satisfactory. Their typographical work is beyond criticism. The fullest degree of cooperation is constantly evidenced. Expressive of their interest and integrity, the President voluntarily advised your Secretary that the printing cost would be reduced thirty-five cents a page during 1932 and if further cost reductions were attainable a still greater reimbursement would be made. This gratifying proposal will produce a printing expense reduction for the year of from \$500 to \$600.

"An added Journal cost has been encountered in the increased number of changes in addresses involving the making of new addressograph plates.

"No charge has been made against the Journal account for correspondence and postage expense incurred in the Secretary's office in discharging the work entailed in the business management of the Journal."

The secretary makes the following recommendations:

"That book reviews in the Journal be limited to publishers who advertise in the Journal. At present publishers receive valuable space at an annual expense to the Journal of approximately \$200 to \$250 per year. Were this space paid for at advertising rates, the annual income would be about \$1,500."

The NEW YORK STATE JOURNAL OF MEDICINE conducts its book reviews as items of scientific information, totally divorced from every business consideration. Every book is reviewed on its merits only, and is condemned if it does not come up to the highest modern standards of practice and literature.

Concerning illustrations in the Journal, the Publication Committee reports:

"The 1931 volume contained 104 half-tone illustrations and 77 line drawings. The cost of these has been borne by the contributors. The editor has drawn attention to instances in which illustrations have consisted of photographs of faces in which there is a possibility of recognizing the subject and suggests that contributors should obtain permission, in writing, to use photographs for illustrations, or to disguise the features so to render identification impossible."

The support given to the editor is mentioned as follows:

"The long experience of the editor has seemed to warrant your Committee in permitting great freedom in the matter of editorial policy. He

(Continued on page 298—Adv. xiv)

ANALGESIC and ANTIPYRETIC ACTION of the CHEMICAL TOLYSIN

AN IMPORTANT COMPARISON

The tables below present important comparisons. These comparisons mark the differences between the salicylates and the chemical, Tolysin, and indicate the superiority of the latter as an analgesic and antipyretic.

THE SALICYLATES (U. S. P.)

- Analgesic and Antipyretic;
- A distinctive and unpleasant taste;
- Cause of nausea and gastro-intestinal irritation;
- Lacking in definite anti-plastic or anti-inflammatory effect;
- Produce less favorable analgesic effect upon muscle, tendon, and joint pain;
- Therapeutic range, in the case of aspirin at least, is less than that of Tolysin; (aspirin has one-sixth the therapeutic range of Tolysin in dogs)
- Frequently the cause of albuminuria;
- Lack of strong uric acid eliminating effect.

Summary: Effective analgesic and antipyretic action but frequency of nausea, vomiting and other unpleasant by-effects make desirable the use of an improved treatment, especially in children (as for example, Tolysin, which is rarely accompanied by unpleasant by-effects common to the salicylates).

TOLYSIN (The Chemical)

- Analgesic and Antipyretic;
- Tasteless;
- Neutral — Tolysin is the ETHYL ESTER of PARAMETHYL phenylcinchoninic acid, a neutral chemical;
- Practically non-irritant — Tolysin rarely produces nausea or vomiting;
- Relatively non-toxic with a wide therapeutic range — six times (in dogs) that of aspirin;
- Exerts a definite anti-plastic or anti-inflammatory effect;
- Semi-specific analgesic action upon pain involving the muscles, tendons, joints or their appendages in contrast to the more general analgesic action of the salicylates;
- Does not harm the heart or kidneys;
- Gives a uric acid eliminating effect.

Summary: Tolysin is indicated especially in acute rheumatic fever, infectious fevers, colds, and grippé, as an analgesic in chronic arthritis, and for pain and fever in children and old people. Its use provides relief practically without the discomforts and by-effects often traceable to the salicylates.

Tolysin is one example of the construction by The Calco Chemical Company of definite chemical compounds which eliminate the disadvantages of older drugs while retaining and adding to their advantages. It is suggested that Tolysin be tentatively prescribed in two or three cases and the improvement in results noted.

has, however, submitted for review most of his contributions, and all of those of which he has had the slightest doubt.

"During the several years that Dr. Dempster has edited the Journal, the cover page has been devoted to a paragraph dealing with some phases of medical practice. Formerly this was written by members of the profession but more recently by the editor himself. The exigencies of the times compel your Committee to recommend the discontinuance of this feature and the utilization of this space for advertising."

TREATING THE INDIGENT IN MICHIGAN

The February number of the Journal of the Michigan State Medical Society contains the text of an agreement for the care of the indigent sick of Muskegon County, located on the west side of the lower peninsula. It is a comparatively rural county, and its county medical society has 68 members. The preamble to the agreement states:

"WHEREAS, the County of Muskegon has been sending to the University Hospital at Ann Arbor, Michigan, for medical, surgical and hospital care persons who are deformed who need operative attention, pregnant women and persons who are ill, none of such persons having funds of their own to secure such treatment and care, and

"WHEREAS, the County of Muskegon has been paying large sums of money for the various items that go with the care of persons so afflicted, and for such other items as transporting the patients to and from Ann Arbor, Michigan, and

"WHEREAS, certain members of the Muskegon County Medical Society did present to the Board of Supervisors of Muskegon County, at its October, 1931, session, a plan that they in co-operation with the two hospitals in the city of Muskegon, Michigan, would take over the care and treatment of such indigent persons as have been heretofore sent to Ann Arbor for treatment."

THE MEDICAL PROTECTIVE ASSOCIATION: Medical service is to be given by an organization known as the Medical Participating Association which is formed under the auspices of the Muskegon County Medical Society, and is composed of those doctors who desire to enter into a contract with the county officials.

THE COUNTY OFFICIALS: The County of Muskegon agrees to pay to the Medical Participating Association the sum of \$10,000 per year for the treatment of 200 indigent cases referred to it by the Probate Court of the County, or if a greater or lesser number than 200 is referred, then the amount to be paid shall be in proportion that the actual number treated bears to two hundred. This money shall be in full payment of all medical and surgical services which the patients may

Modern diets often lack minerals

To-day, authorities are stressing the importance of the essential mineral salts. In addition to building sturdy bones, and blood rich in hemoglobin, these mineral elements aid metabolism and contribute to nervous stability.

Yet many modern diets cannot be depended upon to furnish the proper quota of minerals, and therefore millions of people suffer from the effects of demineralization. Cooking destroys a variable amount of the mineral value of foods—in some instances as high as 76 per cent.

To correct this loss and to remedy demineralization—with its attendant symptoms of nerve fag, neurasthenia, lowered vitality and loss of energy—a tonic rich in mineral salts is needed.

Fellows' Syrup contains the mineral salts of sodium, calcium, potassium, manganese, iron and phosphorus, together with the added metabolic stimulants—strychnine and quinine. Sixty years of clinical experience the world over testify to its value as a tonic.

Suggested dosage: A teaspoonful in half a glassful of water three or four times daily.

require, whether given in the hospital or the dispensary or the home of the patient.

HOSPITALS: The treatments shall be given in two hospitals, the Hacklay and the Mercy Hospitals. The hospital charges shall be \$4.50 per day for bed patients, and fifty cents per day for dispensary cases, to be paid by the County to the hospitals.

DIRECTOR OF MEDICAL SERVICES: The physicians, called the party of the second part, also make the following agreement:

“The party of the second part further agrees that they will appoint a Director and an Assistant Director who shall see all patients admitted to the Muskegon Hospitals and assign said patients to such physician or surgeon as his or her case may require. The party of the second part further agrees that the said Director will keep a record of all patients so admitted to the Muskegon Hospitals by the Probate Court of Muskegon County. The said party of the second part further agrees that the Director will watch the progress of the treatment of cases in the hospitals, with the object of securing additional treatment if necessary, and with a further object of not keeping patients in the hospitals longer than their condition warrants.

“The said party of the second part further agrees that its members will not order any extra service or medicine not covered by the day rate with the hospitals without first obtaining the written consent of the Director or the Assistant Director of the Association.

“The said party of the second part further agrees that when a patient leaves the hospital and is in need of further care then the member thereof having the patient in charge in the hospital will attend said patient in the out-patient department of the hospital in which said patient was confined, and in case of surgical patients who are not able to come to the out-patient department, that then the member having such case will visit the home of the patient to give care and treatment until such patient is able to come to the out-patient department of the hospital in which such patient was confined, without additional charge.”

The plan of the Muskegon County Society may be compared with the New York Welfare Law, which imposes on a county welfare commissioner the duty to provide medical service to those who otherwise would be unable to procure it.

COUNTY HEALTH DEPARTMENTS

Dr. F. P. Foard, Assistant Surgeon of the U. S. Public Health Service, discusses the history of County health departments in the February number of *Colorado Medicine*, as follows:

“The first full time county health department to be organized in the United States—or in the

world—was organized in Yakima County, Washington, on June 1, 1911. North Carolina followed with the second on July 1 of the same year. Progress was slow, however, in having the different states adopt the county unit plan and comparatively few were organized until after the close of the World War. The county unit plan has been fostered by the Rockefeller Foundation and the United States Public Health Service through financial assistance extended to those counties desiring such organizations; and on January 1 of this year there were 557 counties in the country which were conducting efficient and highly satisfactory local health departments. The average annual increase has been fifty-two counties each year for the past five years. Considering that there are still about three thousand counties in the United States which have no efficient local public health programs, the progress is still slow; yet it is faster than appropriations are being made by Congress to meet the demands for cooperation. The states leading in the number of counties having full time county health units are Alabama first, with 54; Ohio second, with 46; Kentucky third with 43; Tennessee fourth, with 42; North Carolina with 39; Georgia, Virginia and Mississippi all have above thirty, and the other southern states have slightly fewer in number. In the west, California has 13, Washington, 8; New Mexico, 8; Oregon, 8; Arizona, 6; Montana, 4; while several of the western states and many of the New England states have none. New York, however, has recently submitted a law which if passed will make it compulsory for every county in the state having a population of more than forty thousand to maintain a full-time county health unit.

"Tennessee, one of the poorest states in the Union from the standpoint of assessed valuation of rural property and per capita wealth, has one of the most efficient, if not the most efficient, state health departments in the country."

FEDERAL MATERNITY LEGISLATION

The principle of Federal aid to the States in public health work, embodied by Congress in the Sheppard-Towner Act, was in practical operation for a number of years until the Act was repealed by Congress June 30, 1929. Since that time attempts to pass a similar law have been made by its proponents in every Congress. The present bill was introduced in the Senate by Senator Jones of Washington and by Representative Bankhead of Alabama. The *Texas State Journal of Medicine*, with other State Medical Journals, is actively opposing the bill, although Mr. Sheppard, the author of the former bill, is senior senator from Texas. The leading editorial in the February number of the *Texas State Journal of Medicine*

GENERAL BAKING COMPANY

420 LEXINGTON AVE., New York, N.Y.

(Continued from page 302—Adv. xviii)

enumerates seven reasons for its opposition to the bill as follows:

"1. The Sheppard-Towner Maternity and Infancy Act, as passed originally and later modified, failed to materially speed up the decline in the maternal mortality rate during the time of its operation, and there has been no increase in mortality from this source since the law was repealed

"2. The re-enactment of this measure would, in our estimation, add unjustifiably to the burden already borne by federal and state taxpayers. This would seem not to be the time to increase federal expenditures for any but the most necessary purposes, and who is there who can say that this purpose is necessary at this time, particularly in the face of the united if not unanimous opposition of the largest and most influential group of physicians in the world?

"3. If this type of legislation continues to grow in popularity, the time will soon arrive when some of our states will find it exceedingly difficult if not impossible, to match Federal funds.

"4. The measure represents a most insidious but certain approach to state medicine, so-called, of the most reprehensible type, reprehensible in that it invades, indirectly and, in prospect, directly, the practice of medicine in states, counties and municipalities, all under federal direction and control.

"5. The medical profession is opposed to the socialization of medicine rather because of the anticipated ill effects upon the dependent public than upon the welfare of its own members.

"6. The legislation provides very practically for Federal control of a broad scope of activities in the state, at the expense of both state and federal taxpayers.

"(a) A Federal board is created, comprising the Surgeon General of the U. S. P. H. S., as chairman (doubtless designed to relieve the apprehension of those interested in public health matters), the Chief of the Children's Bureau of the Department of Labor, and the Commissioner of Education of the Department of the Interior,—two to one in favor of lay control.

"(b) The board is given the power to 'approve or disapprove of all plans for cooperative work between the United States and the several states under the Act,' which is equivalent to saying that the Board may direct these activities, for all practical purposes.

"(c) The purpose of the measure is declared to be two-fold, first (so placed as good psychology) to enable the Public Health Service, 'under the general supervision of the Board' to 'co-operate with the state agencies of health in the development of local health units or organizations for the prevention of disease and the promotion of health among the rural population'—second, the purpose of 'enabling the Children's Bureau, under the general supervision of the Board (al-

ways) to cooperate with the state agencies of health promote the health and welfare of mothers and children'

"(d) The element of coercion is carried by the terms of the appropriation. It is provided that no funds appropriated under the Act shall be made available to the states until an equal sum shall have been made available by the state first for the promotion of the first purpose of the bill and second for the promotion of its second purpose both of which we have just recited. But that is merely the foundation. Any state desiring to avail itself of the benefits of the appropriation authorized by the measure must secure the approval of its plan for carrying out the purposes of the law, in addition to appropriating one half of the cost of the entire work.

"(e) Apparently the author of the measure has anticipated and disarmed the opposition of such organizations as christian scientists, antivaccinationists, and the like by requiring that the plans for the states shall provide that 'no official, or agent, or representative of the state in carrying out the provisions of this Act, shall enter any home or take charge of any child over the objection of the parents or either of them'

"(f) The Children's Bureau, it is provided,

shall withhold allowance to states for maternity and child welfare work under this measure, 'upon request of a majority of the Board'

"7 Finally let it be understood by all who would know that in opposing the legislation under discussion the medical profession departs not one jot or tittle from its traditional concern for the health of the public"

MEAT INSPECTION IN MISSOURI

The February issue of the Journal of the Missouri State Medical Association discusses editorially the relation of the St. Louis Medical Society to meat inspection, as follows:

"It was long known to the members of the St. Louis Medical Society that the City of St. Louis had no effective ordinance for inspecting local packing houses. The Society's committee on health and public instruction viewed the situation and decided to recommend a campaign to establish municipal meat inspection. The committee was composed of Drs. Charles E. Hyndman, Jerome E. Cook and Robert Vinyard and instructed the executive secretary, Mr. Elmer H. Bartelsmeyer to make an investigation and report the result to the committee. Mr. Bartelsmeyer

carried out these instructions and made a detailed report. He found fourteen plants in St. Louis whose products entered into interstate commerce and therefore enjoyed Federal inspection but he also found forty-eight plants whose products were sold wholly within the State and therefore had no supervision either by the Government or by the City of St. Louis. Approximately 50 per cent of the meat and meat products consumed in St. Louis were not inspected or were very inadequately inspected.

Indicative of the danger to the public health Mr. Bartelsmeyer submitted the following figures: During the fiscal year ending with June, 1930, there were 1,750,855 cattle, calves, sheep, goats and swine slaughtered in St. Louis plants under Government inspection; of these 3,862 carcasses and 25,794 parts of carcasses were condemned because of a diseased condition and 79,210 pounds of meat and meat products were condemned for improper handling. In comparison, the report pointed out that 521,604 animals were killed for state consumption in plants without Government inspection and with no record of carcasses or parts of carcasses condemned on account of disease or improper handling.

"Growing out of the work begun by the committee the packing establishments having Government inspection sponsored a meeting at which a civic committee of ten, the St. Louis Committee on Inspection of Meat, was appointed by the group at large. On this civic committee was Dr. T. B. Pote, St. Louis, United States Bureau of Animal Industry, and the executive secretary of the St. Louis Medical Society."

The editorial describes some of the difficulties met and obstacles overcome in securing an effective ordinance on meat inspection, and a system of its enforcement. The editorial concludes:

"The establishing of meat inspection is of prime importance to anyone interested in the people's health. But aside from the forward stride in community health there is another angle that is gratifying. The public in St. Louis demanded meat inspection. The story of the passing of the ordinance is that of a small group, the committee on health and public instruction of the St. Louis Medical Society, making the public conversant with the facts that they were not getting inspected meats and that inspected meats were healthier and could be had. It is also the story of the wisdom of a medical society employing a layman as an executive secretary."

SECTIONAL MEETINGS IN MINNESOTA

An editorial in the October number of *Minnesota Medicine* defends sectional meetings of the physicians of groups of counties as follows:

(Continued on page 307—Adv. xxiii)

(Continued from page 306—1st. xxi)

"More than eighty practitioners of Medicine registered at Hibbing and attended the fine day's session of the Northern Minnesota Medical Association. Despite the depression and oppression, the attendance from such a wide area was, as ever, a fine indication of most doctors' zeal for instruction and organization, and enjoyment in fraternizing with their fellows.

"No one can see in such amplified sectional meetings, or what are virtually yearly assemblages of contiguous county society groups, any interference with the purposes or prerogatives of the State Association. It seems necessary at times to reiterate this opinion because the notion abounds that defections, through hospital staff meetings, special groups, or the great colleges detract interest and support from the official groups leading up to the American Medical Association. This notion is not denied by those who neither attend hospital staff meetings nor like them, men who are supposed to remain away from state and American Medical Association meetings because they ingest medical pabulum to satiety at home. Go to all these meetings, and you will find the sturdy veterans in the benches at all the good meetings. To locate the rest for present or future, is not the purpose of this editorial."

BUDGET OF WEST VIRGINIA

The February issue of the West Virginia Medical Journal carries the following comments on the budget of the West Virginia State Medical Association which was adopted by the Council on December 29, 1931 —

"The item of salaries includes the salary of the executive secretary, the stenographer, the treasurer, and also provides for additional stenographic help if needed. The item for legal services is the amount of the annual retainer paid to the Association attorney. The item for traveling expense covers such expenditures of councilors and officials who make trips on official business for the Association.

The complete budget as adopted on December 29 follows:

Salaries	\$5 400 00
Library	150 00
Rent	480 00
Telephone Telegraph	170 00
Postage	250 00
Traveling Expense	300 00
Convention Expense	400 00
Legal	100 00
Office Supplies	200 00
Office Maintenance	150 00
Stationery	150 00
Miscellaneous	250 00
Total	\$8 000 00

It's Always SUMMER for INFANTS on S.M.A.

—because S M A.
prevents Rickets
and Spasmophilia.

SUMMER sun is an effective anti rachitic agent but the physician cannot always depend on it, so he usually prescribes cod liver oil.

However, it is sometimes difficult to get the infant to accept cod liver oil, whereas it is easy to give it to him in the form of S M A — a dependable automatic method of preventing rickets.

For infants deprived of breast milk, S M A is a close adaptation to breast milk, with the advantage that it contains enough biologically tested cod liver oil to prevent rickets and spasmophilia and the additional advantage that this cod liver oil is uniformly distributed in each feeding and is properly emulsified for easy assimilation.

S M A is not only simple for the mother to prepare but also simple for you to prescribe, relieving you of exacting detail in infant feeding.

Physicians have prescribed S M A for more than 250 000 infants with excellent results.

Don't you want to try S M A in your own practice? A trial supply with feeding suggestions is yours for the asking.

What is S. M. A.?

S M A is a food for infants—derived from tuberculin tested cows milk the fat of which is replaced by animal and vegetable fats including biologically tested cod liver oil with the addition of milk sugar potassium chloride and salt altogether forming an antirachitic food. When diluted according to directions it is essentially similar to human milk in percentages of protein, fat, carbohydrates and salt in chemical constants of the fat and in physical properties.

SECRETARIES' CONFERENCE IN MINNESOTA

Many states now hold annual conferences of their county secretaries. That of Minnesota is described in the February issue of *Minnesota Medicine*, as follows:

"The three major events of the morning program included discussions of fee collection methods led by Mr. Albert Wilson of St. Paul; a recital of the work of the joint cooperating committees of the Minnesota Editorial and the Minnesota State Medical Association by Mr. Roy J. Dunlap, Managing Editor of the *St. Paul Pioneer Press and Dispatch*, and J. A. Watson, chairman of the Medical Association Committee, Minneapolis; and a symposium on Medical Care of the Poor under the chairmanship of Dr. Theodore Sweetser, Minneapolis, chairman of the State Health Relations Committee. W. C. Andrews, Frederic, Wisconsin, president of the Polk County Medical Society; Mr. Vernon D. Blank, Des Moines, general manager of the Iowa State Medical Society, and Dr. Harold M. Camp, Monmouth, Ill., secretary of the Illinois State Medical Society, reported on the systems in use in their respective states. The Hon. Henry Benson, Attorney General, commented upon possibilities of introduction into Minnesota of the contract system in use in Iowa and elsewhere for the care of the poor.

"The luncheon address on the subject, 'The County Society Turns the Tide Against State Medicine,' was made by Mr. H. Van Y. Caldwell, Cleveland, executive secretary of the Cleveland Academy of Medicine, with a discussion by Mr. Theodore Wiprud, executive secretary, Milwaukee County Medical Society.

"The afternoon program was devoted exclusively to Periodic Medical Examinations and Medical and Hospital Care for Veterans, the latter occupying the major portion of the time."

MEDICAL CARE OF INDIGENTS IN IOWA

The care of indigents in Iowa by contract of County Boards of Supervisors with their County Medical Societies has been described in this Journal several times, as in that of March 15, 1930, page 368. The February number of the Journal of the Iowa State Medical Society summarizes the development of the plan to date as follows:

"The completion of three new county medical society contracts for the care of the indigent sick brings to nineteen the total of such contracts in Iowa. The recently completed contracts are in Crawford, Monroe and Tama counties. In each of these counties the project has been in process of formulation for nearly three years and the successful consummation is a source of satisfaction to all concerned. In the smallest of these, Monroe county, the contract is for \$1,000 a year, in Tama county the sum is \$2,000, and the Crawford county contract is for \$2,500.

"Reports already received indicate that the sixteen counties previously having contracts have renewed them for 1932, some with increases. The Muscatine county contract has been increased to \$3,600, and the Webster county contract has been increased from \$3,000 to \$3,615. The Scott county contract remains at \$15,000. Final reports have not been received from the remaining counties but preliminary indications are that renewal at previous figures have been effected in Black Hawk, Boone, Clinton, Hardin, Jefferson, Lee, Louisa, Mahaska, Marion, Marshall, Pottawattamie, Washington, and Wright counties. The Iowa plan is receiving attention in other States. The attitude of Michigan is indicated in an abstract printed on page 298 of this Journal. What a County Medical Society may do will depend largely on its state laws.

HEALTH INSTRUCTION THE BEST SOCIAL INSURANCE*

By RAY LYMAN WILBUR, M.D., SECRETARY OF THE INTERIOR, WASHINGTON, D. C.

YOU and I are units in a great living mechanism we call civilization. Our lives are particles in a flowing stream of human energy which goes on indefinitely, but to each of us is granted but a brief period in which we must pass through infancy, adolescence, maturity and senescence. Whether we go through the whole individual cycle or drop out by the way, whether we contribute or are carried along depends upon the inherent vital forces with which we are endowed by birth and the incidental happenings which come our way. Health is a term we use to express a state of well-being and a capacity to do. It means more than the absence of evident disease. The presence of health in mind and body determines the height to which individuals may climb and nations aspire. Each conscious person has the day to day task of living in a certain physical frame. He can not transfer to a new one. He can not be sent back to the factory for new and up-to-date parts. The surgeon gets along better taking things out than putting them in. Each person must work with what he has in the way of body equipment. By understanding his own body, and by knowledge of pertinent facts, it is possible for each to steer a course with the minimum of friction and the maximum of results. Organized groups of individuals either as families, communities or nations, may likewise use facts in going forward. We no longer consider ourselves mere creatures responsive to gods and demons requiring propitiation. The entrails of animals tell us today the hard facts of science, and guide us in the control of living organisms which are harmful to us. We no longer look to them for an augury of good or evil.

Through centuries of patient and clear-eyed study we find ourselves custodians of information that has made a new world possible. The grip of terror that has held man tight since the dawn of life has been loosened for what we call civilized peoples, but it has by no means been eliminated. We have many of our enemies classified and

named, but in each of us lurks the savage with his fears and credulity. The label on a patent medicine bottle is as soothing as the advertisement is provocative. We want to believe that a few ground up husks in a handsome carton will give us health for a few cents instead of earning well-being by care, sane conduct and the use of expert information.

In the forefront in the advance of science has been the physician seeking to use each new discovery for the relief of the pain and distress of those calling upon him for help. Discovery has been added to discovery. With well digested experience and a multitude of clinical observations, there has been an astounding growth of fact knowledge for the guidance of society in the domain of sickness and health. In the unraveling of the tangled and confused manifestations of disease we were fortunate enough to find certain weak spots subject to mass attack. Instead of permitting a community to acquire immunity to the typhoid bacillus through the tragedy of illness, we destroy that organism in drinking water with chlorine and control it by heat and measures of cleanliness in milk and other food products. We destroy the mosquito that gives us malaria, we let the calf provide us with vaccine to control smallpox, and meet and conquer natural enemies in a thousand fields. Each year there is a growth of this fact knowledge with a constant change in emphasis and in method as we learn more and more.

In spite of the prodigious progress in the field of public and of private health, in spite of anaesthesia and modern surgery, we find a considerable number of our people refractory to the opportunities given them by science. Our organization for the application of knowledge to the immediate needs of an individual or of a community is still inadequate and has never been founded on a sound basis of economics. Besides, in each of us there still remains some remnant of the old belief in magic and in a certain number, magic completely replaces science.

If society is to advance through the advance of

* Address to the Sixty-seventh Convocation of the University of the State of New York, at Albany, New York, October 15, 1931.

health, we must prepare the minds of our boys and girls so that they will know not only what to expect but be able to distinguish the genuine from the false. This can be done through the teaching of health and hygiene. This is an easy phrase to say, but it describes one of the most difficult forms of education. Each human being is a law unto himself. There is a great variation in the topographical anatomy of the body, in the physical resistance to disease, to drugs and to narcotics, in the tone of the muscular system, and in the power of the nervous system to control the body and to handle itself. For each, many of the lessons of health and hygiene must be separately learned. There are, of course, many conditions which are practically universal, which are favorable or unfavorable to the health of the body. The removal of unsatisfactory and dangerous conditions in environment, the development of sound health habits, the understanding of proper body nutrition, all can be taught with confidence and success. Hygiene is no longer a series of don'ts. It now must be lived as do's. It must be positive, not purely negative. The wide margins which the body possesses so that it will have the capacity to undergo strain, must be understood, but must not be taken advantage of. Knowledge must replace precept. Physiology must be simple and understood. One does not need to become conscious of everything that his body does, nor to develop into a hypochondriac but he should know the whys and wherefores of ill health so that he can avoid sickness and build up natural strength.

The community can well arrange to have a health survey of all of the facilities that it provides and also of the health condition of each of its citizens. Whether this is brought about by volunteer effort, through industry, or through the public school or all working in unison, is not so important as it is to have a complete physical examination of the community and of each of its citizens at various intervals. This examination, if properly handled and interpreted, is the best source of health education. The Health Department can constantly educate the community by the way in which it does its work and by the publicity given to it.

We have come a long way from the period when the nose was considered the best way to discover the source of disease, but ignorance is still the greatest opponent of sound personal and public health. If in our public school we can teach the facts of health, we can see a new generation facing with understanding the problems of the body and free from those fears that have haunted the human race throughout the ages. Health education should be approached from the standpoint of health rather than from that of disease. Fortunately, we can rest on basic scientific discoveries; we can get down to fundamentals. I am reminded of the story that came out

of the State of New York at the time of the Food Administration in Washington. In one of the debates before a committee a man from upstate New York who tired of voluminous but somewhat vague discussion said: "Up in our part of the State we have a theory that the man who sleeps on the floor can not roll out of bed." I think it is about time for us to get down to the floor on this topic which we are discussing. That there are firm foundations is not appreciated by all. Too many of our people become mentally fuzzy in their discussion of health problems; too many of them consider themselves experts, since they have had the experience of living with and operating an active living unit for a certain number of years. They feel that their experience can be a universal guide. But science is a better one.

As I have already said, the great variability between individuals makes it necessary to deal in broad terms and in averages in connection with much health instruction, health advice and health services. We can look into the past and see how the physician has steadily risen on the backs of thousands of men like Franklin, Pasteur, Koch, Jenner and Edison until today he can look out over much conquered territory in spite of the blurred horizon where our research workers are busy. We no longer need to speculate and guess in many fields of health. We know, for science has taught us. It is true that we must present an even changing front as new information comes in. Most important of all is it, that our children shall get a biological viewpoint in looking at life.

Probably our greatest difficulty is that there is no way to account for much of human behavior. There is no way to tell what a human being will do the next minute, or what he is going to do in the future. Each action is a creation of the moment. Health becomes then not a study of the mathematics of structures, but of the control of forces. This applies not only to the individual but also to the social organism. Perhaps the best contribution that can come from health instruction is associated not only with the receptivity of the prepared mind of which we have spoken, but the ability to see and to understand.

From the standpoint of public health, there is much that can be done for the public. There is though, much that the public alone can do for themselves. How much the public will do depends upon how much they know. How much they will be able to absorb of the existing knowledge depends upon the kind of training they have had in schools. Unless they have learned to recognize the significance of fact it is not likely that they can be guided in the right channel. It is true that through the law and public health administration we can use the method of "don't" or "verboten" in handling many health problems, but that way is only partially effective. The control of units, whose actions are individual and

under the steering power of but one will can be brought about only by a true understanding of facts. In other words, we can say that where "George can do it," public health is well done, but where the person must do his share the problem is and will remain one of great difficulty.

Looking at the various forces operating in our country for the improvement and advance of our society we naturally turn to education as the most dependable method to get results. We are grasping the fact that education is not a mere transfer of information from one mind to another, but that it is a manifold process by which a growing person learns how to operate under his own power and will. Particularly in the sphere of health, we must learn by doing, and what we do must be

done with understanding. It is impossible to picture what might come to us as a race if we could take full advantage of all that is now known and useable in the control of public health and in the promotion of personal health and well being. It is inevitable that we will drag along a considerable remnant of past thinking, of old fears and inhibitions, but with widespread health education this residue need not be the controlling factor in public health activities.

Reason, example, experiment, observation in the field of nature study and biology will lay that solid basis for health which is needed. Society can get greater dividends in happiness, comfort, security of home and community from applied health knowledge than in any other way.

MEDICAL RESEARCH*

By FREDERICK G. BANTING, M.D., TORONTO, CANADA

WHEN I received the kind invitation to address this Convocation, the fact that it would give me an opportunity of visiting the ancient and historical city of Albany greatly influenced me in accepting. Albany has occupied a unique position in the mutual history of United States and Canada. It has been associated with the romantic episodes of early exploration since the time of Hudson. It seemed to me therefore, that the field of exploration in which I am most interested namely, Medical Research, could be fittingly discussed in Albany.

Most of you are acquainted with the outstanding results of Medical Research. Pasteur, Lister, Ehrlich, Flexner and Minot are well known names and the results of their work have had a profound effect on the daily life of people of all civilized countries. As a result of Medical Research, diseases one by one, are being controlled, treated and cured. Smallpox, typhoid, scarlet fever, diphtheria, diabetes and pernicious anemia are no longer to be dreaded.

The lives of the outstanding men of Science are an inspiration to us today. The results of their work are being applied in our every day life to preserve the health of humanity. The scientific truths discovered by them are the foundations on which our Science of today is built.

There are still many problems to be faced by the Medical and Scientific world. The greatest interest of the moment is not what has been accomplished but in the task of the future. We still have many diseases which baffle the medical profession. Advancing civilization with its in-

dustrial development is introducing new problems which must be solved.

The greatest need of Medical Research at any time is men. We need have no fear of a situation if we have man power and brain power to meet it. It is my purpose today to speak to you about the "Research Worker."

Research men are born, not made. The research man is fundamentally inquisitive—not about things that everybody knows, but about things which nobody knows. The child starts out in life with an inquisitive mind but the average child is satisfied and contented by the answer given by an adult. The child soon loses that inquisitive quality if he is suppressed. As a child grows older it is not always in his best interests to answer his questions but he should be encouraged to answer them himself as far as possible. In 1923 I visited the City of Washington and had the pleasure of meeting an eminent physician of that city. He told me that every Saturday morning he took his two boys, of 6 and 8 years for a walk. On one occasion the two boys plied their Daddy with questions until he became displeased and told them that they must not ask so many foolish questions, but that they must think before asking. When they arrived at the zoo they went to see the lions and after some time the older boy asked "Which is the daddy lion?" His father told him that it was the one with the mane. On thinking it over the child said, "I don't think you are quite right about that, Daddy. Mother's hair is longer than yours." I would like to follow the career of that child, for he has the making of a research man. His answer also involved a fundamental principle in Research—the

* Address to the Sixty-seventh Convocation of the University of the State of New York at Albany, N. Y. October 15, 1931.

challenge of authority. He did not accept without due consideration the explanation given to him.

There is no doubt that many children who have natural research minds lose the gift by improper training or lack of cultivation. Our modern school system with the large number of children placed under the care of one teacher, and the standardized course of training does not permit of encouraging originality, but great care should be taken not to suppress it.

People who have not an investigative mind will never make research workers. They may be useful and accurate in routine work but they seldom have a worth-while idea.

Research workers must have imaginative minds and natural powers of observation. The essential qualities to be looked for in a Research man are honesty, common sense, balanced enthusiasm, self-confidence, tenacity, system and method in keeping notes and in planning and carrying out experiments, and unreserved devotion to the problem in hand. If a man is not honest he may deceive himself and be led to draw conclusions from false results which will not stand repetition by other workers. If a man lacks common sense he is liable to be easily side-tracked, and is led to do foolish things in the name of Research. If a man does not possess enthusiasm, he very soon becomes lazy and gambles away his time, but if he becomes over-enthusiastic, he may become carried away and arrive at conclusions too hastily. If he lacks self confidence, he can never convince himself or others of the value of his work. The young worker must not become discouraged even if the trend of experiment goes against theory. If he has not the tenacity to continue he will often miss out and, because of incompleteness, his work will fail. The Research man who lacks method and system is like a ship without a rudder. The young worker who has not an unreserved devotion for his work is not likely to succeed. I am a firm believer that if a person tries hard enough and long enough, he will achieve whatever he reasonably sets out to do.

A man's worth in Research should not depend on his personality but it does become a very important factor, because cooperation with other workers is essential in most research problems. The young worker who is adaptable has a great deal in his favor for he will get more assistance from other workers and they in turn will come to him for advice.

There are many applicants who present themselves to a department of Medical Research, and it is of the utmost importance, especially if means and facilities are limited, that the best should be selected. It is an advantage to inquire into the history and school record of the candidate. As a rule the man who has been head of his class is not the most desirable. Such a student has usually a "memory" mind. He has a highly trained

memory and can reproduce lectures and textbooks at the examinations in a literary style that delights the teacher. He is equally good in all subjects for they are all one to him. The Research man is more apt to come about one-third of the way down the list in his class standing. He is outstanding in one or two subjects and in the others he has secured a pass. There is in a certain laboratory a brilliant and most promising Research student whose record is an example of this type. During the three years at the Agricultural College he was considered a very mediocre student. The College required a thesis on some farm topic during the third year. This student selected "Wool" as his subject. When he produced his thesis it was of such outstanding quality that no professor felt sufficiently acquainted with the subject to assay its true value. The thesis was sent to a practical wool authority and he said it was the best article he had ever read on the subject, for it contained much information new to him. The boy was sent for and questioned as to the source of his knowledge and under cross-examination he told of his experiments and observations. His thesis had marked him as a true Research man and he was given every opportunity to develop his talent. Through the kindly influence of his professor, he has taken up Research for his life work.

On the other hand another student came to the laboratory a short time ago and wished to do Research. There was no special problem in which he was interested and he was quite indifferent to several that were suggested to him. He had graduated in Medicine two years ago and had held a Research scholarship in Clinical Medicine since that time. His class standing throughout the Medical Course had been high. As far as I was able to learn, his Research Work had consisted in pure routine analysis. Research scholarships are wasted on students of this type. They may do excellent work in some other field but high standing alone does not qualify them for Research work.

As I said before, I believe that Research workers are born, not made, but I also believe that proper training can help a great deal. Possibly the greatest thing that a teacher can give a student which will help him in after-life is inspiration. There are teachers who impart to their students the love of the subject and an interest which they carry beyond the school-room. A great number of Research men are produced in the high school where some kindly, inspiring teacher stimulated their imagination, aroused their curiosity and trained their powers of observation. The teacher in the high school can advise the student what subjects are essential for his training for future usefulness. When the student begins his study of the Sciences—Mathematics, Physics and Chemistry, he is apt to neglect the Languages. Every student should ob-

tain a reading knowledge of French and German in high school. German is the most important to the Research man because so many scientific articles are written in German.

The majority of scientific workers have had the Research talent awakened at the university. Of all the courses in the university the Medical Course provides the best training in the powers of observation, deduction and recording of findings. The Medical Course not only teaches Medicine but tends to produce an all round training which may be well applied in other walks of life. For this reason we have outstanding sculptors, artists, poets and authors among the alumni of the medical schools. The Medical Course tends to develop the best that is in the man and tends to stimulate his creative instincts. Towards the final year the undergraduate who has the Research mind usually selects subjects which are of most interest to him. Very often this interest has been stimulated by his admiration for the professor as much as by the subject itself. In my own case it was a teacher on the Surgical Staff of the University of Toronto who instilled in me the desire for post-graduate work in Surgery. It is in post graduate work that the real training for the Research man is obtained. The student who remains for a year as a junior in any department of the university is usually given a small amount of teaching but his major work in such departments as Physiology, Pathology or Biochemistry is a Research problem. It naturally follows therefore that the manner in which the student is treated in his first actual taste of Research will be important all through his life. The professor who allots a day's work to his post-graduate students and comes around the following morning to collect the results is doing great harm to his student. I have in mind an eminent professor who has had from 4 to 8 undergraduates under him every year for 20 years and who never produced an outstanding Research man. On the other hand he has produced routine technicians.

I believe that the student should be allowed to work on his own problem if he has one, or if a problem is given to him he should make it his own. He should be given every assistance in the working out of the problem but he should be made to plan his own experiments, draw his own conclusions and consult the professor for suggestions or advice. The reading of the literature on the subject should be left in the student's hands but he should be warned to read all scientific articles in the most critical and analytical fashion. Too much reading of the literature is not to be advocated. Too thorough a review of the literature, before beginning work, is inadvisable for there is scarcely a subject in medicine on which there is not a wide diversity of opinion and confusion of thought. After completing the Research work the student will be able to evaluate the experimental results that are related to

the problem. When the work is completed the young Research student should write his own report, giving his results and any conclusions that may be drawn. If the paper is published, it should be published in the name of the worker or if it is reported at scientific meetings the paper should be given by the worker. In this way the student learns that he will get out of his work advantages in direct proportion to the energy which he puts into it.

At the present time there is a vogue for obtaining post-graduate degrees. In every laboratory there are M.A. and Ph.D. students engaged in Research. The student believes that the Ph.D. degree gives him a rank and standing which will enable him to better his position. Since almost all universities prescribe Research work in their Ph.D. degree these students present themselves to the laboratory. Many of this type of student have not the qualities to make them Research men. Much time is wasted in the effort to try to make them something that they are not. Possibly one of the worst features of the post-graduate degree is the thesis which is frequently published.

The young Research man can be assisted by training him in observation, in the careful and accurate recording of his results, and a careful supervision of the methods in his work. He should be encouraged to put down his ideas in a note-book so that he can refer to them and think about them before trying experiments. The young worker should be given as much latitude as possible in his work, but he should feel that he can discuss his problem with the professor at all times. He should not be laughed at and his ideas should be treated seriously, however foolish they may be and as far as possible, he should be made to answer his own questions. The young Research worker will greatly be helped by discussing his problem in perfect confidence with some person in whom he has absolute trust. The mere telling about it often clarifies the idea itself.

This was my own experience as a post-graduate student under the late Professor C. L. Starr. It is impossible to describe in words what he gave to me, but I know of no man of whom it may be more truly said, "What you are speaks so loudly that I cannot hear what you say." I always got encouragement and inspiration from Dr. Starr and never left his presence without feeling stronger and better able to carry on. He was an idealist and unconsciously imparted this idealism to those who were associated with him. I recall at least a dozen outstanding surgeons who owe much of their success, both in practice and Research to the influence of the late Dr. Starr. I can give no better advice to the ambitious Research man than that he should seek out such unselfish leadership.

The teaching departments of a medical school may be equipped with good teachers who are not

necessarily good Research men. It is unfortunate that these two qualifications are not always combined. We still have with us teachers who have a mind like an encyclopedia and who have the idea that knowledge is power. These men demand that the student memorize facts and place a premium on memory rather than on originality. The head of a department who is not interested in Research should not have contact with students. No matter how excellent a teacher may be, if he does not instil into his students the desire for investigation he can never be a success. The greatest need of our colleges is men with Research minds. Teachers often make the excuse that they have not time for Research but such an excuse is invalid. The person who wants to do Research will always be able to find time. The head of a department may not have time to do all the technical work necessary for his problem, but if he is the proper sort he will either provide himself with a technician or interest his students to carry on such work under his direction.

The ideal place for carrying out Medical Research is in a medical college, for there are very few problems today which do not require laboratory facilities. Most of the larger problems in Medicine involve special knowledge of more than one subject and it is an advantage to be able to consult and exchange ideas with the heads of the various departments in a medical school. Cooperation is the keynote for successful Medical Research. The work on Insulin was started in the department of Physiology; the department of Biochemistry assisted in the chemical work on depancreatized dogs; the Connaught Laboratories took up the manufacture; methods of administration were investigated in the department of Pharmacology, and later the department of Medicine carried on the clinical investigation.

Research in its broadest terms is the search for truth. The truth in Science can be found only by trial or experimentation; but before the trial is made there must be a reason for its execution. This is to be found in an idea. The idea is the most valuable thing in Research. Ideas never come to a man who accepts everything he hears without mental reservation. They never come to the careless nor to those who never ask why. They never come to the man who is satisfied with Science as it is today. Ideas come only to the man who asks why and who tries to answer his own questions. They come to the man who thinks about the facts that he reads and observes. It is not the man who has knowledge alone who becomes the Research man, but rather the man who is able to utilize the knowledge which he has. Knowledge alone is not power. Thinking is power. Ideas cannot be forced or called forth at will. There must be some influence which stimulates thought. Human disease is a constant challenge to the Research man in Medicine.

There is inherent in the Research man the desire to overcome obstacles, desire for achievement and the desire for the betterment of Science. Competition must not be underrated as a stimulus to thinking. Some of the world's greatest thoughts have been the outcome of criticism from an enemy.

My personal experience has been that ideas come in the quiet hours of night when one is free from outside disturbance. It is true that there are moments free from work during the busy day, but there is no possibility for continuity of thought when one does not know when an interruption may occur. Ideas come when one is in familiar surroundings, free from the distraction of the newness of things. One does not have ideas if one is physically or mentally tired. On the other hand, quietude, restfulness and peacefulness of the occasion will not produce thoughts without the stimulation for the desire of personal accomplishment. Even if the surroundings are conducive to thought there is no guarantee that quiet thinking will produce a constructive idea. I do not think it is possible to make a habit of thinking but very often one idea leads to another. New facts give further food for thought.

Important ideas often come as strange coincidences: for example, on the night of October 30, 1920, I was preparing a lecture on the Physiology of the Pancreas, during the early part of the evening. It occurred to me that there was a possibility that it was the external secretion of the pancreas which destroyed the internal during the process of extraction. Before retiring I read an article by Moses Baron describing the damage produced in the pancreas by the obstruction of the duct by gall stones. This article pointed out that similar damage could be produced by tying the pancreatic ducts. It has always been my habit to ponder over and critically analyze an article. It suddenly occurred to me that the external secretion could be got rid of by tying the ducts and the internal secretion would thus be separated. It was a coincidence that the two articles were read at the one time; otherwise they might not have been co-related and the idea which was the beginning of the experimental work on Insulin might not have been produced.

Once the idea has been formed the next step is to experiment to prove or disprove it. In some cases it may not be possible to begin this experimentation for some time, but if the idea is worthwhile, delay will only increase enthusiasm. Work was not begun on Insulin for five months after the idea was obtained. During this period further reading and further thought enabled me to crystallize the idea into experimental form.

Once the work was commenced there were no new major ideas until the first idea had become a fact. It required from April until August to

prove that there was an internal secretion of the pancreas and that it could be extracted.

The second idea in connection with the development of Insulin arose under the following circumstances: It required seven weeks and the life of one dog to provide enough Insulin to keep a depancreatized dog alive for one day. Best and I had a dog to which we had become very attached. This dog was at the point of death for want of insulin. All the available source of insulin from duct-tied dogs was used up. Unless we could get insulin from some other source the dog would die. In response to the seriousness of the situation I sat down alone in the middle of the night and with the new knowledge gained from our experiments I began to think of related facts. An old class-room experiment was recalled to my mind and I immediately concluded that by the long continuous injections of secretin, which is made from the intestinal mucosa, the pancreas might be exhausted of its supply of external secretion. The following morning this experiment was carried out. It was a great satisfaction to Best and myself that the extract produced in this way restored our pet dog to normal once more. Further efforts to make extract in this manner were not so satisfactory, but the knowledge gained from this experiment was of an advantage in providing additional proof of the original hypothesis.

During the next two months serious obstacles arose which obstructed our progress. It became necessary to either stop the work or procure some new means of obtaining insulin. While reading some notes made the previous winter I found an article which had no application to the earlier work but which proved of great value at this time. An anatomist by the name of Laguesse had stated that there were more islet cells in the pancreas of the new born than in that of the adult. This observation represents the value of fundamental research. It had had no practical application for 10 years but it became the starting point for a chain of ideas which were essential in the development of insulin. Within twenty-four hours of re-reading the article we had an abundant supply of insulin made from the pancreas of foetal calves which were obtained free at the abattoir, and it was not long until we were able to extract insulin from the whole adult beef pancreas. Insulin is an example of the application of fundamental research on practical problems. In all research the fundamental must be first, and although the world at large attributes honor and

fame to the worker who contributes to the practical welfare, it is to the quiet research worker on fundamental problems of science that we owe the most.

Many valuable ideas are lost because they are not carried far enough in quiet thought to be resolved to experimental basis and then worked out. When work is commenced on any problem the new experimental data give rise to new ideas, further experiments and further work. The more one works on a particular subject the more one finds to do. It is like education—there is no end to it. Pasteur was one of the hardest workers the world has ever known. He lived, moved and had his being in his laboratory and all other interests were secondary to his work. Once when he was a guest at the palace of Napoleon III, he was expected at a tea given by the Empress. When the guests had all assembled Pasteur was missing. He was found in his room engrossed in the microscopic study of the Royal wine. Pasteur never failed to advise young students to work. Addressing a group of Edinburgh students he said, "Ever since I can remember my life as a man, I do not think I have ever spoken with a student for the first time without saying to him 'work perseveringly'; work can be made into a pleasure, and alone is profitable to a man, to his city and to his country."

Through the ages there has been accumulated a vast amount of knowledge. Facts have emerged from fiction by trial and experimentation. Never has there been such an impetus to Science as at the present time, and never before has there been so much hoped for and expected of Medical Science. Too frequently we judge the prosperity of a country by its trade and commerce, but to my mind there is no better barometer of national progress than Science and Research. Dumas, the eminent French chemist and teacher of Pasteur said, "The future belongs to Science; woe to the nations who close their eyes to this fact." Pasteur resounded the same chord when he said, "Science has no nationality because knowledge is the patrimony of humanity, the torch that gives light to the world. Science should be the highest personification of nationality because of all the nations, that one will always be foremost which shall be first to progress by the labors of thought and of intellect. Let us therefore strive in the peaceful field of Science for the preeminence of our several countries. Let us strive, for strife is effort, strife is life when progress is the goal."

DIAGNOSIS AND TREATMENT OF SYPHILIS

(FROM THE VIEWPOINT OF THE GENERAL PRACTITIONER)

By A. B. CANNON, M.D., NEW YORK, N. Y.

This address was delivered at the headquarters of the Bellevue-Yorkville Health Demonstration in New York City in connection with the Syphilis and Gonorrhea Campaign conducted during October, November and December, 1930, by the Bellevue-Yorkville Health Demonstration in cooperation with the New York City Department of Health, the New York Tuberculosis and Health Association and the American Social Hygiene Association.

DIAGNOSIS OF SYPHILIS FROM INITIAL LESION

REGARDLESS of his particular specialty every physician frequently has to exclude syphilis as a possible diagnosis. There are few diseases which affect so many different organs of the body as does syphilis, and few which simulate so great a number of other diseases.

While most of us are able to recognize a typical initial syphilitic lesion when it appears on the genitals, sometimes the sore is without appreciable infiltration and so small and superficial that we are unable to state positively that the lesion is luetic until after we have made a dark-field examination. The diagnosis may be rendered more difficult also by complications with gonorrhea, chancroid, herpes, or granuloma inguinale, and, occasionally, tuberculosis.

When we recall, though, that the initial lesion of syphilis more often appears on the prepuce, is especially common at the frenum, that it is usually hard with a central erosion or ulceration, and that it is very often associated with glandular enlargement,—we feel justified in making a diagnosis of syphilis in the presence of these symptoms.

FIGURE 1

Typical chancre showing hard swelling with superficial erosion.

Every initial lesion in syphilis is a productive growth or tumefaction, whereas every tertiary gummatous lesion is essentially a destructive or necrotic process. Usually the incubation period of syphilis is approximately 21 days. A week after the appearance of the chancre the glands draining that sore become enlarged, and by the end of the fifth week, those on the opposite side are involved. After the sixth week there is often a pharyngitis and a secondary macular eruption on the trunk and flexor surfaces. Oftentimes, from the character of the secondary skin eruption—macular, papular, grouped or follicular, one can calculate the approximate date of the patient's exposure, a point which may be of considerable importance in finding the source of infection and in making a prognosis.

While it is rare for one to have high fever with secondary untreated syphilis, I have known cases with a temperature fluctuating between 101 to 105 degrees.

Not infrequently a patient will present himself with a hard phimosis and a characteristic gonorrheal discharge in which gonococci can be demonstrated. Such a phimosis is very suggestive of a syphilitic infection complicating the gonorrhea, and when it is associated with an inguinal adenopathy of a non-suppurative type, one can be practically certain that the patient has a syphilitic infection. The diagnosis usually can be confirmed by making a dorsal incision or circumcision, and a dark-field examination from the probable ulcer underneath or from the sclerotic foreskin. One may also aspirate one of the enlarged inguinal glands and make a dark-field test from the material obtained. Cases showing enlarged inguinal glands usually have positive Wassermanns, while those in which sufficient time has not elapsed for the glands to be affected, have negative ones. We believe that 95 per cent of the cases showing a non-suppurative type of inguinal adenopathy are syphilitic, irrespective of the clinical appearance of the penile lesion.

The diagnosis of syphilis may further be obscured by chancroidal infection. Not only may the penile lesion have every characteristic of a chancroid, but not infrequently it is also complicated by ulcerating buboes. In such cases, syphilis may not even be considered until the appearance of a secondary syphilitic eruption, pharyngitis, alopecia or some other form of secondaries. It is necessary in such cases to do frequent dark-field tests and, in addition, to take weekly Wassermanns.

FIGURE 2

Chancre (mixed infection) and chancroid. Note the erosions of glands and the sclerosis of the prepuce and the enlarged inguinal gland.

When she returned to the same clinic a week later, the sore was larger, but after a consultation with two other doctors, she was again reassured and told that the lesion was only an aggravated fever sore.

FIGURE 3
Chancre of lip.

It is much more difficult to diagnose a chancre in a woman than in a man, especially where the sore appears on the cervix or the vaginal wall. In fully 95 per cent of the female patients at the City Hospital suffering with early syphilis the diagnosis was not made until after the appearance of secondaries, or the finding of a four-plus Wassermann. The syphilitic chancre, when located on the cervix, may show only a red swelling or a superficial erosion.

The extragenital chancres have in the main the same physical appearance as genital chancres; but because of their location on other mucous or skin surfaces, their true nature is not suspected until the occurrence of secondaries. They are apt to be larger and often more tumor-like, as are also the glands which drain these lesions. While the lips are the most frequent sites of extragenital chancres, we see them on the tongue, tonsils, fingers, face, rectum and suprapubic region.

A few years ago, a man presented himself at the Vanderbilt Clinic with an initial lesion at the bend of the elbow. It was found that he worked in a candy factory on an eight-hour shift, and that two other men carrying the same candy bucket had similar lesions in which spirochetes were demonstrated.

A young woman, aged twenty-five, called to see me a few months ago with a large indurated sore on her lip. I found the submaxillary gland draining the sore the size of a lemon, hard but not painful. There was also a maculo-papular eruption over the body, and a sore throat. The young woman was a child's nurse. Two weeks previously she had gone to a clinic, where she had been assured that the lesion was a fever sore.

To be on the safe side, we should consider every enlarged non-suppurative gland draining a sore—irrespective of the character of the sore—syphilitic until we prove by a dark-field examination and blood Wassermans that it is not.

DIAGNOSIS FROM SECONDARIES

We pass now from chancre to secondary manifestations. The physician knows—as pointed out previously—that the earliest form of syphilitic skin eruption is a macular rash usually appearing on the forearms and the sides of the abdomen, where the skin is most tender; and that as the disease becomes more advanced, the lesions grow papular, scaly, grouped, and sometimes pustular or follicular. Later on, the lesions diminish in number, and group themselves on the extensor surfaces or on surfaces where there is friction. These changes are brought about through blood-vessel involvement.

Macular syphilis usually has to be differentiated from pityriasis rosea. The latter disease has a "bathing-suit" distribution; the lesions are arranged along the lines of cleavage of the skin, but the macules are usually finely scaly; there is often an initial plaque, and the eruption is slightly pruritic.

Papular syphilis sometimes resembles lichen

FIGURE 4

Secondary syphilitic eruption showing macular and papular eruption.

planus, but the latter usually occurs on the flexor surfaces; it is a very pruritic disease; the papules are violaceous in color, flat-topped and shiny.

Any papular eruption involving the soles, the palms, the forehead, around the mouth, and the labio-nasal junction is suggestive of syphilis.

One late manifestation of secondary syphilis is a grouped, follicular and papular type usually appearing about six months after the initial sore, on the trunk and especially on the back, simulating lichen scrofulosus, a tuberculous condition. The primary sore and the glandular enlargement have most often disappeared by this time, but the skin eruption is diagnostic.

Another manifestation diagnostic of late secondary syphilis is the condyloma latum. While, as you know, this may manifest itself on any portion of the cutaneous surface where there is heat and friction, it is usually found in the folds of the buttocks or in the groin, and appears as a raised, flat plaque or a moist papule. This is to be differentiated from the condyloma acuminatum, the elevated warty lesion occurring in the same locations. Spirochetes are easily demonstrated in the secretions taken from condylomata lata.

TREATMENT

Having established the diagnosis of primary or secondary syphilis with the aid of the dark-field examination and the positive Wassermann reaction, we immediately put the patient on one of

the arsphenamines, mercury, or bismuth. I should suggest beginning with an injection of arsphenamine. A healthy strong man may be given 0.25 or 0.3 gm. of neoarsphenamine and one grain of mercury salicylate. I should repeat the neoarsphenamine injections every other day for the first six doses, then at three, four, five, and six-day intervals, making a total of ten doses, the last four of which should consist of .4 gm. each. The mercury is repeated at five to seven-day intervals, until fifteen injections have been given, being continued after the completion of the arsphenamine course. At the end of each full course, a Wassermann test should be made. Then the arsphenamine is begun again, the first six doses being given at semi-weekly intervals and the remaining four at weekly intervals. At the completion of the foregoing course, the patient is given fifteen more injections of mercury followed by another course of arsphenamine, continuing in this way until he has had 30 doses of arsphenamine and 45 of mercury—all without a rest period. During the time that the patient is receiving the mercury injections, I usually prescribe 30 to 90 grains of potassium iodide daily by mouth. Following the second course of arsphenamine, a spinal fluid examination should be made.

It is necessary to give at least one full course of 10 arsphenamine and 15 mercury injections after one has obtained a negative Wassermann. In early syphilis, the Wassermann is usually negative after one full course of treatment. Provided the foregoing outline is strictly adhered to, the Wassermann usually remains negative and the patient is free from symptoms.

After treatment is discontinued following a negative Wassermann, the patient is asked to return for a blood test three times at two-month intervals, then twice at three-month intervals, then once every six months for three years. Following that, as a precaution, a complete physical examination and a blood test should be made once a year. I also recommend that each patient have an x-ray picture of his heart made before beginning the treatment and after its completion.

To return from treatment to diagnosis: Nearly all tertiary lesions of the skin, as well as those involving the mucous membranes, are deeper and more infiltrated than secondary lesions, and are oftentimes ulcerated. The tertiary lesions are also fewer in number, and when appearing on the skin, usually involve the extensor surfaces.

A man forty-one years old consulted me because of a large, red pustular nose condition of a year's duration. He had been treated for acne rosacea with twelve x-ray exposures, colonic irrigations and vaccines without appreciable change. We noticed on examination that many of the papules were fleshy, extended into the mucous membranes of the nose, and on to the upper lip. There was a tender swelling over the lower third

of the anterior surface of the left tibia. An x-ray picture of this swelling showed periostitis. The patient also had an aortitis and a four-plus Wassermann of the blood. The nose lesions and the periostitis cleared up under antisyphilitic treatment.

FIGURE 5

Tertiary syphilis of nose previously diagnosed as acne rosacea.

Another interesting case was that of a white man, age 65, builder, who came to me complaining of multiple ulcerations. He had been unusually healthy, not having had occasion to consult a doctor for forty years. His wife was well. He had two healthy grown children, and grandchildren. He stated that the lesions had begun on his right shoulder as red, raised, ulcerated areas, gradually creeping over most of the trunk and the extremities; as they healed in the center they spread at the margins. Within the past three months an ulcer on the right leg had become so deep and so annoying that he had to seek medical advice.

Examination showed a ruddy-faced man, well developed and well nourished, and appearing not more than fifty-eight to sixty years of age. There was marked scarring involving practically the entire upper right side of the body and about three-fourths of the left side. On the right buttock was a large horseshoe-shaped dark-red ulceration, the central portion consisting of scar tissue. The right lower extremity markedly enlarged appeared about twice the size of the left, and presented rather hard scarred tissue with a verrucous formation around the ankle, dorsum of the foot, and lower third of the leg. Even these warty areas were ser-piginous in outline. On the inner and upper aspect of the right knee and invading the thigh

was a deep oval ulceration, whose diameters measured about four and five inches respectively. The central part of the ulcer was composed of irregularly-shaped, bleeding, dark-red granulations. The margins were elevated, hard in some portions and moth-eaten in others. Heart, lungs and abdomen were essentially negative. Blood pressure 158/84. Pupils and deep reflexes were equal and normally active. A clinical diagnosis of multiple gummata was made, but inasmuch as the lesion on the inner aspect of the right knee was suggestive of carcinoma, a section was taken for histologic examination. This showed a squamous cell epithelioma. The Wassermann reaction was strongly positive by both methods, as was also the Kahn precipitation test. Part of the lesion improved to a marked degree under mercury and neo-arsphenamine injections and potassium iodide, but another part remained unchanged. A second piece of tissue was removed, and the report on this confirmed the previous one of carcinoma. The ulcer was then widely removed by means of the endothermic knife under local anesthesia; following this, the wound and adjacent portion of the thigh were treated with massive doses of x-rays. As a result, the patient has continued to improve, the ulcer having practically healed.

FIGURE 6

Carcinoma in a syphilitic scar

To my mind this case is of interest in that the man had no history of a venereal disease, that he went for so many years in perfect health except for the marked ulceration and scarring, and that he did develop a carcinoma on the site of irritation of a gummatous lesion.

A case showing marked destruction of soft parts and periosteum with deformities.

A woman (single, aged thirty-eight, house-work) was admitted to the City Hospital about a year ago, complaining of ulcerations of the feet, legs and forehead. During this period she had been treated by three different physicians, the last one referring her to the Hospital. She had not been able to walk for about eight months because of deformities of the feet. From examination it was noted that there was marked ulceration and scarring. The skin over the front of the legs was absent, leaving the tendons exposed. There was contraction of the toes and feet, with marked destruction of tissue. There were also several deep ulcerations of the forehead extending up into the scalp-hair. X-ray pictures showed marked periosteal destruction and an osteitis. The Wassermann was four plus. While the ulcerations gradually healed under treatment with arsphenamine, bismuth, and potassium iodide, the woman was partially crippled because of the marked destruction of soft parts and bone. It is obvious to all of us that such a condition as this case now presents could have been avoided if a blood Wassermann had been taken in the beginning and antisyphilitic treatment given at the onset.

It is the frequency with which we meet such

cases in hospital, clinic and private practice that prompts these illustrations of the advantages of considering all chronic ulcerations—especially those involving the bone as well as the soft parts—as due to syphilis until proved otherwise.

Another case illustrating the marked destruction caused by syphilis is the following:

A man aged thirty-nine years presented himself at the Vanderbilt Clinic eight months ago with a total destruction of the nose and adjacent soft parts. About a year previously he had had a small ulcer on the nose. A physician whom he consulted prescribed ointments and salves. The ulceration gradually spread. After two months the patient discontinued treatment with the physician and applied a patent medicine to the ulcer. It is hard to conceive that an American-born individual of apparently average intelligence, and speaking English as well as this man did, should allow so prominent a portion of his anatomy to be destroyed without making a greater effort to seek medical advice.

FIGURE 7

Gumma of lower extremities with marked deformity.

FIGURE 8

Gumma showing destruction of nose and upper lip.

You will recall that such a destruction of soft parts, cartilage, and bone is characteristic of a syphilitic infection; whereas tuberculous infections, with which syphilis is so often confused, produce destruction of the soft parts only, leaving the cartilage of the nose intact, and resulting in the characteristic pointed nose one sees in lupus vulgaris.

While carcinoma will cause a destruction similar to syphilis, the time required is much longer than in syphilis; besides, there is usually the foul odor, the nodular, mother-of-pearl appearance of some

part of the border, with hardness and telangiectasia.

The lesion in the case under discussion has entirely healed, and just as soon as we have obtained a negative blood Wasserman, we shall turn the patient over to a plastic surgeon

PERFORATING ULCER OF THE HARD PALATE

An American-born white man aged twenty-seven years was referred to me by his nose-and-throat specialist about a year ago for a small perforation of the hard palate of twenty-four hours' duration. He was married and had two healthy children. The family history was negative. He denied venereal infection. He said that about a year previously he had consulted his nose-and-throat specialist because of a sore inflamed throat and a small pimple on his hard palate. His Wassermann reaction was reported doubtful. A section of the lesion on the palate was diagnosed by a pathologist as tuberculosis. Some light treatment applied to the throat was followed by temporary improvement. After a short while, however, the lesion grew worse, and he was sent to Saranac, where he remained for six months. He returned to the city to all appearances entirely well. About two months later, the condition recurred, and he again consulted a throat specialist, who resumed the light treatment. His throat rapidly grew worse after the second treatment, and in twenty-four hours after the last exposure to light, a small round hole appeared in the palate.

Examination revealed a split-pea sized perforation in the mid-line of the hard palate. There was redness and swelling of the surrounding portion

of the hard palate extending to the soft palate and the uvula. I believe it is generally conceded that such a perforation of the palate is pathognomonic of syphilis. The patient's Wassermann reaction was returned four plus and his condition cleared up rapidly under arsphenamine and mercury injections. Of course there remained a hole in the hard palate. Every hour's delay in beginning treatment in such a case helps to increase the extent of the destruction, and the possibility of its leading to a perforation of the palate.

Probably it occurs to all of us that the obvious thing to have done in the beginning of this case

FIGURE 10
Gumma of tongue

was to give the patient the benefit of anti-syphilitic treatment, especially inasmuch as he had a doubtful Wassermann reaction. While it was unfortunate that the physician should have been misled by the laboratory diagnosis of the specimen taken from the throat, it is well known that both clinically and histologically, late lesions of syphilis may sometimes so closely simulate tuberculosis that a definite diagnosis is impossible without corroboration by the Wassermann reaction or a therapeutic test.

SYPHILIS OF THE TONGUE

Practically every late syphilitic ulceration of the tongue must be differentiated from carcinoma and sometimes from tuberculosis. Fully 95 per cent or more of carcinoma of the tongue are caused by inflammatory conditions due to there is

FIGURE 9
Gumma with perforation of the palate.

smooth atrophy, leukoplakia and interstitial glossitis, which constitute positive evidence of a syphilitic infection. A gummatous ulceration of the tongue is a rare occurrence, whereas carcinoma on a syphilitic basis is a common one. The evolution period of a gumma is relatively short, and the ulceration is oftentimes deep, with considerable destruction of tissue, and sinus formation, associated with a moderate amount of inflammatory reaction. There is usually very little pain. As you recall, carcinoma is a productive nodular growth, exceedingly hard and painful; where ulceration is present it is superficial and bleeds easily. Usually there is little difficulty in differentiating the hard nodules of carcinomatous growth from the gumma, but where the diagnosis is doubtful, it is far better to clip off a small portion of the growth for histological examination.

The patient with carcinoma of the tongue associated with syphilis is all too frequently given antisyphilitic treatment over a period of weeks or months, thereby losing very valuable time. As we all know, arsenic is a decided epithelial stimulant, and oftentimes hastens the growth of the carcinomatous tissue.

FIGURE 11

Carcinoma with leukoplakia smooth atrophy and interstitial glossitis.

SYPHILIS OF THE PALM SIMULATING ECZEMA

A man aged forty-three years, American-born, consulted me for an eczema of one palm and a

radium burn over the front of the wrist and adjacent portion of the palm. His family history was negative. He denied venereal infection. He stated that he had had a thickened wart-like scaly condition of the palm for three years. He had been receiving radium for one year. After the last radium treatment, two months previously, his whole hand and wrist had become swollen; the swelling was followed by a painful ulceration, which had gradually extended. He had had no other symptoms.

Examination revealed a thickened warty, scaly and fissured condition of the left palm and palmar surface of the fingers, sharply demarcated from the surrounding healthy skin. There were no papules. Over the front of the wrist and adjacent portions of the palm there was a deep ulceration one and one-half inches in diameter, necrotic, with bleeding points, and excruciatingly tender. Physical examination showed evidences of an aortitis, with widening of the aortic area on percussion, and a loud, accentuated and roughened second sound. Blood pressure: 110/45. He had Argyll-Robertson pupils. The deep reflexes were absent. The urine showed an almost solid coagulation of albumin, and an occasional hyalin and granular cast. While a unilateral, dry eczematized and sharply demarcated condition of the palms and palmar surface of the fingers is evidence in itself of a tertiary syphilitic infection, in this case—as in most instances—there was additional corroborative evidence of syphilis to be found on complete physical and neurological examination. The diagnosis made in this case was: tertiary syphilis of the palm, syphilitic aortitis, tabes dorsalis, syphilitic nephritis, and radium burn. Needless to state, the so-called eczema of the palm cleared up rapidly under specific treatment, as did also all evidences of nephritis.

SYPHILITIC PERIOSTITIS AND OSTEITIS FOLLOWING AN INJURY

A man twenty-six years old was seen by Dr. Alan DeForest Smith at the Orthopedic Hospital and later referred to the Syphilis Department of Vanderbilt Clinic for a deformity of the wrist. He said that two months previously he had been struck on the wrist by a baseball while playing. His wrist became greatly swollen, hard and slightly painful, with limitation of motion. X-ray pictures showed periostitis and osteitis. His Wassermann was reported strongly positive. The condition entirely cleared up following anti-syphilitic treatment. It is a well-known fact that gummata usually form at the site of irritation or injury. Gumma involving skin and bone is usually seen at the elbows, knees, and on the shins and buttocks. Even acute paresis and locomotor ataxia have been known to follow a severe accident or injury. Knowledge of such cases is of

great importance in diagnosis, from a clinical as well as from a legal standpoint

ANEURYSM

A white man aged fifty six years came under my observation some three years ago for a questionable diagnosis of aneurysm. He had been married for thirty years. His wife was well and they had four normal, healthy children. He stated that some twenty-five years ago, he had had a small penile lesion, diagnosed as chancroid. He had never been treated for syphilis. He had always been very active and perfectly well except for occasional slight indigestion. His symptoms had begun three months previously, following an automobile accident. He did not think that he had been badly hurt but from this day on, he had neuritic pains in his left shoulder, of a sharp, stabbing character, and shooting down his left arm to the ends of his fingers. He was treated for a few weeks for stomach trouble, without improving. An x-ray of his stomach showed a large tumor in the mediastinum. Fluoroscopic examination indicated an aneurysm of the aorta. His Wassermann test was moderately positive (two plus). He was given two injections of sulpharsphenamine intramuscularly, the first dose of 0.1 gm being followed two weeks later by 0.2 gm. After the first injection he was greatly improved. The pain and discomfort had entirely disappeared. After the second injection, however, all the symptoms recurred in an aggravated form. The pain grew worse, he began to expectorate blood and to have a slight dyspnea. A second x-ray and fluoroscopic examination showed the aneurysm to be a size larger. He was then brought to New York.

His local internist was unable to find any evidence of an aneurysm, either on percussion or on auscultation. Two well known x-ray men differed as to whether the large mediastinal tumor was an aneurysm or a new growth. We felt, however, that the history, location, and character of the pain, increase in size of the mass following salvarsan treatment, the expectoration of blood and the positive Wassermann reaction furnished sufficient evidence upon which to base a diagnosis of aneurysm, and this diagnosis was confirmed by fluoroscopic examination.

This patient was kept in bed at one of the local hotels for several months, during which he received injections of mercury and bismuth every three days, and potassium iodide by mouth. He returned home greatly improved, and after a few weeks stopped all treatment. For a period of two years he was able to go about his work and was very comfortable. Finally, while driving his car on a fifteen hundred-mile trip he ran twice into a ditch and was considerably shaken up. Two or three weeks after returning home, he had a slight hemorrhage through the mouth, remained

in bed for a week, and then returned to business. A few days later, he arose one morning, went to the bath-room, and there had another hemorrhage. This time he bled about two quarts and died within fifteen minutes after the onset of the hemorrhage.

We have seen so many similar cases, in which patients with aneurysm improved after from one to three or four injections of arsphenamine, and then suddenly became very much worse. For this reason we have discontinued the use of arsphenamine in the treatment of aneurysm, other than in exceptional cases. Instead, we rely almost exclusively on mercury, bismuth, and iodide, and—whenever possible—rest in bed. I have a record of one man with an aneurysm who was treated in this way for thirteen years, during which time he led a fairly active and comfortable existence.

CITATION OF A CASE OF NEUROSYPHILIS

Syphilitic infection of the nervous system is, as you know, one of the most serious phases of the disease, and probably one of the most interesting to diagnose and treat.

A man aged sixty two years consulted me about three years ago complaining of faulty vision, unsteady gait, impaired powers of concentration, and a general feeling of physical and mental depression. About eleven months previously he had gone swimming at Long Beach on a particularly rough day, and had been beaten by the waves. As he did not feel quite right after this experience, he went to his insurance company for a thorough examination. This was recorded normal except for a two plus Wassermann reaction of his blood. During the succeeding nine months he consulted five excellent internists, all of whom gave him written statements to the effect that his condition was normal for a man of his age, and that his blood Wassermann was negative. He continued to feel bad, however, and since he had also a great deal of difficulty in reading, he consulted an eye specialist who could find nothing wrong with his eyes.

My examination showed slight inequality of the pupils, one reacting a little sluggishly to light. All of his deep reflexes were hyperactive, the right patellar being a bit more active than the left. There was a Babinsky of the right foot. Physical examination of his heart was essentially negative. His blood pressure was 164/90.

On the basis of these slightly abnormal neurological findings, I told the man that I was sure he either had at the time an active neurosyphilis, or that he had had a syphilitic infection of the nervous system. I was not so much interested in a negative or positive blood Wassermann as I was in the results of his spinal fluid tests. My laboratory findings showed his blood Wassermann to be two plus with cholesterol, negative with the alcohol, his spinal fluid showed Cells

36, Globulin: 3+, Wassermann: 4+ to 0.5 cc., Gold Sol.: 4332110000.

I immediately began treatment, giving him 10 neosalvarsan, 8 tryparsamide, 15 bismuth, and 6 intraspinal injections. He made a remarkable improvement, both physically and mentally. His gait improved so that he was able to dance, a thing he had not done in ten years. He could think and remember much more clearly and he felt physically alert. He discussed his case with a friend, who told him that it was impossible that he should have such an infection, and advised him to consult his physician, who happened to be a well known specialist on arthritis. After being examined and having his blood tested, he was given the usual negative report, stating that he had never had syphilis. This information greatly agitated the patient. I suggested that he consult the chief syphilologist of one of our leading medical schools. He did so, with the result that he was given another letter advising him that his blood was negative and that he had no signs of syphilis. He then returned to this syphilologist and told him his entire story, including the fact that I had been treating him for syphilis of the nervous system. He was then referred to a well-known institution in this country, where, after a thorough examination, he was assured that he not only had positive signs of an infection of the nervous system, but that, although his blood was negative, his spinal fluid was positive, and his condition called for more intraspinal treatment. He returned to me with this report and resumed his treatments. I think that such a case not only shows us the fallacy of attempting to rule out a syphilitic infection without a very thorough examination, including spinal fluid tests, but also illustrates the splendid clinical and serological results that can be obtained in certain types of neurosyphilis by means of intraspinal treatment with the Swift-Ellis serum.

DISCUSSION

Q.—Apart from cases of aneurysm, do you think mercury and bismuth are better drugs to use in the treatment of cardiac syphilis?

A.—Yes; I think that both drugs are valuable in practically all forms of syphilis, especially in cases where the infection has been present for many years. In such cases, where long periods of treatment are necessary to secure a negative Wassermann, and in elderly people suffering from the disease, where arsphenamine is contraindicated, bismuth, mercury, and potassium iodide are the only remedies used.

Q.—What physical characteristics have rectal chancres?

A.—The same as any other chancre,—namely, an infiltrated or hard ulceration, oftentimes associated with fissuring, and enlargement of the inguinal glands, particularly on the side of the lesion.

Q.—Do you ever use sulpharsphenamine?

A.—No. Arsphenamine is about two and one-half times more potent than sulpharsphenamine and is less toxic. I believe that arsphenamine should be used in cases where one is unable to give an intravenous injection.

Q.—Is it justifiable to use sulpharsphenamine in aneurysms of the heart and aorta?

A.—No. Its action is just as dangerous in this type of syphilis as are the other forms of arsphenamine intravenously.

Q.—Do you give arsphenamine in cardiac syphilis?

A.—Only in selected cases and in very small doses, and where I am able to observe the case carefully.

Q.—Is mercury salicylate the best form?

A.—I think it is the best form of the insoluble mercury compound.

Q.—Is it not a fact that the pain is due to the mercury not going into the muscle?

A.—Yes; this is oftentimes the case; but it is far more frequently due to the lack of vigorous massage to the parts after the injection.

Q.—In a case of syphilis of the liver with ascites, where the abdomen fills up within a few weeks after tapping, do you think salvarsan is the drug of choice?

A.—While I believe that mercury, bismuth and iodides are the drugs of choice, I think in exceptional cases, where carefully observed, arsphenamine intravenously is beneficial. We are treating such a case at the Vanderbilt Clinic at the present time with arsphenamine, and the woman has improved considerably. A bile index, Van den Burgh, and blood chemistry are necessary before beginning, and frequently during the course of treatment.

Q.—Do you think that the gumma precedes or follows trauma?

A.—I believe that the impairment of the tissue due to injury, plus the presence of the spirochete, is the cause of the gumma.

Q.—Is a provocative salvarsan of any value in congenital syphilis where there is a definite history in the older children?

A.—I don't think so, unless the child has a gummatous lesion.

Q.—What would you advise in a family of children where the older ones have a syphilitic infection with positive Wassermans and the two younger children have negative Wassermans?

A.—If the two younger children have no stigmata of congenital syphilis, nor any other evidence of a syphilitic infection, and their Wassermann reactions are negative, I should not treat them. At least a yearly examination and Wassermann test should be made.

Q.—Do you do a spinal puncture on all of your cases of syphilis?

A.—Yes, always.

Q.—If the blood Wassermann is negative, is it necessary to do a spinal fluid test?

A.—Yes. It frequently happens that a patient has a negative blood Wassermann and a strongly positive spinal fluid. I recently saw a man complaining of a progressive deafness of a year's duration. There was no history of venereal disease, and his blood Wassermann had been reported negative by several laboratories. His physical and neurological examinations were reported normal. His spinal fluid Wassermann, cells, globulin, and gold reactions were strongly positive.

Q.—Can you make a diagnosis of syphilis of the nervous system where only the pupils are pin-point and fixed to light?

A.—Yes; only syphilis, hydrophobia, or morphine poisoning would produce such pupils.

Q.—What kind of neurosyphilis gives you large, unequal and fixed pupils?

A.—Basilar meningitis.

Q.—Where the spinal fluid is strongly positive will sufficient salvarsan reach the spinal fluid by intravenous injections to cure the condition?

A.—No. Usually, if a person has a four-plus Wassermann to 0.2 cc., no amount of intravenous treatment will affect the spinal fluid. The treatment must be by Swift-Ellis or by malaria.

Q.—In your routine treatment of syphilis, do you give mercury and salvarsan on the same day or alternate the two?

A.—For the convenience of the patient, I frequently give them the same day. In old syphilitic infections, such as tertiary, I usually give mercury and salvarsan in separate courses.

Q.—In latent syphilis, if no symptoms are present and there is only a four-plus blood reaction, do you give salvarsan more than once a week?

A.—Usually once a week.

THE CONTROL AND MANAGEMENT OF THE CARDIOPATHIC CHILD

By EDWARD L. BENJAMIN, M.D., NEW YORK, N. Y.

From the Cardiac Department of the Lebanon Hospital.

ABOUT ten years ago, in 1921, the number of cardiac children attending the Pediatric Clinic at Lebanon Hospital, increased to such an extent that we were confronted with the problem of taking care of these children in a special way. With the view of bettering their condition, the Cardiac Clinic for Children was organized—the first clinic of its kind in Bronx county. Heretofore these children attended the Pediatric Clinic at irregular periods and no organized effort at supervision had been attempted. Here was a type of child that required special supervision and a systematic control of its life at school and at home. It was found that many of these children were suffering from a cardiac involvement, with the many manifestations of rheumatic disease, had little or no follow-up care and that the supervision of their school activities and home life was insufficient, inadequate and desultory. With the view of improving all these conditions and helping these unfortunates, the Clinic was established, in conjunction with special Cardiac classes in five different schools and with the aid and cooperation of our Social Service Department. All children with cardiac defects or symptoms suggesting potential cardiac disease were referred to our Clinic by school physicians for classification and treatment. In other words, the Clinic became a sort of clearing house for cardiopathic children.

On admission these children were given a general examination and all defects and possible foci of infection, such as hypertrophied and diseased tonsils and adenoids, carious teeth, chronic

sinusitis, anemia and malnutrition, noted. They were then sent to special departments for the correction of these defects, X-ray of heart and lungs taken to determine size and shape of heart and presence of any pulmonary lesion, classified and requested to report at the clinic at regular stated intervals. They were then followed up by the Social Service nurse from week to week, and the home conditions as well as the physical condition of the child supervised. These examinations at regular periods served as an excellent opportunity to observe and study the progress of the cardiac condition, the various rheumatic manifestations, and the intercurrent infections in these children.

The classification we followed is that formulated by the Association of Cardiac Clinics, and has proven of great assistance in classifying these children. It consists of five classes:

Class I. includes children with organic heart disease who are able to carry on habitual physical activity without discomfort.

Class II. includes those with organic heart disease who are unable to carry on habitual activity without discomfort. (A) Slightly diminished physical activity. These children show fatigue, palpitation and dyspnoea on attempting ordinary physical activity. Their activities are consequently slightly diminished. (B) Greatly diminished physical activity. These children show signs of heart failure on the slightest activity and consequently their activities are greatly diminished.

Class III. includes those with organic heart disease who are unable to carry on any physical

activity. These children show symptoms of heart failure at rest and generally have an active heart infection.

Class IV. includes those who show abnormal signs or symptoms referable to the heart, but in whom the picture of heart disease is uncertain. These are classed under "Possible Heart Disease."

Class V. includes those with a predisposing history, such as chorea, rheumatism, and frequent attacks of tonsillitis. These are classed under "Potential Heart Disease."

Despite the above classification we have frequently found it necessary to deviate from it, especially when we realized that each cardiopathic child was an individual problem. And the most difficult, and by far the most important, problem was to classify a child definitely as a cardiac. Those who have been associated with this type of child can appreciate what it means to condemn one to the narrow confines of a cardiopathic life as a result of an error in diagnosis. We have found that, rather than stigmatize such a child and limit his activities forever, that it is better to err to his advantage, if the case is on the border line and indefinite. The classification and management of these cases was governed not so much by refinements of examination, but by the history and etiology in each individual case. The cardiac condition, while important, was only secondary to the many manifestations of the rheumatic condition present. Our aim was to delve into the conditions underlying or causing the cardiac damage. Children sent to the clinic with the complaint—shortness of breath, on slight exertion, and pain over precordium—even though examination revealed a systolic murmur at the apex, not transmitted—but with no history of infection or any rheumatic manifestation—were not classified as organic, and relegated to the cardiopathic class. It is the tendency of many physicians to call such cases organic, a decision, I think, that is hasty and without foundation. However, any child with a history of growing pains or frequent attacks of tonsillitis, who, on examination, shows a systolic at the apex, even though not transmitted, and with no change after exercise or position and heart sounds good—such a child should be classified as a cardiopathic, i. e., rheumatism with cardiac involvement. For this type of child, sooner or later, if not properly supervised, will show a much greater involvement and cardiac decompensation. We have observed many cases with tachycardia, dyspnoea, anemia—with a systolic at apex, not transmitted—with no rheumatic history, improve remarkably well when placed under general tonic treatment and not subjected to the regime of the cardiopathic child.

In differentiating organic from functional murmurs one should pay particular attention not

only to the kind of murmur, but to the place where best heard—the point of maximum intensity—and to the variability on change of posture. Functional murmurs are very fickle—they are never the same at all examinations—the vacillating and shifting character of them being the determining factor, in addition to the past history, in differentiating them from organic murmurs. The systolic murmur of organic disease, however—where there is a history of rheumatism, or where there is no history but a cardiac enlargement is present—generally is not shifting in character, is very definite, and is transmitted to the axilla.

There is another type of child that is brought to the clinic very frequently—the child with tachycardia—which presents a problem in diagnosis as well as treatment. This class of child enters the clinic with the diagnosis of heart disease made by his mother generally. These children are of neurotic temperament, are very easily fatigued, have precordial pain, palpitation and dizziness, are depressed, irritable and apprehensive, do not sleep well, have cold extremities, sweat profusely, and have a mottled skin. Examination usually reveals the tachycardia—which often continues for four or five minutes after rest—no irregularity, no murmurs, no cardiac enlargement, but a nervous child with poor circulation and an exercise tolerance which is far below normal. This condition frequently referred to as irritable heart is functional and may often be traced back to some contagious disease or to neurotic parentage. These children should not be classed as cardiopathic, despite the symptoms simulating those of cardiac decompensation. They represent a type of child which is seen in many children's clinics and they all show this neuro-circulatory weakness, which sometimes is the flare of hypothyroidism or tuberculosis. In following up and observing this type of child for the past few years, we have found that most of them improve remarkably well with a change in environment—convalescent care in the country—medication having no effect on their condition whatever.

As regards convalescent care for the cardiopathic child, I should like to take this opportunity to mention the wonderful co-operation and aid we have obtained through the kindness and courtesy of the different convalescent country homes—the Martine Farm, Irvington House, the Pelham Home and Nichols Cottages—in giving these children convalescent care throughout each year. These periodic recuperative stays in the country tended to improve their general health, provided them with a greater resistance to withstand the further onslaughts of the rheumatic infection, and aided them in the progressive improvement of their condition.

I should like to say a word about the various

tests devised and employed in classifying these children. The value of these exercise tolerance tests in cardiopathic children has been variously estimated. Stair climbing, dumbbells, and knee bending tests have been utilized as a basis for the measuring and the regulation of the functional efficiency. We have employed the dumbbell test in our clinic because of its ready adaptability and convenience. The swinging of dumbbells of known weight a certain number of times until maximum effort has been reached—as manifested by dyspnoea, fatigue and flushed face—has served as a good criterion in most instances to measure functional efficiency. This has also been supplemented frequently by the stair-climbing test, the result of which, of course, we had to depend upon the statement of the child and its mother. The spirometer also was utilized in measuring the vital capacity of the lungs, thus giving us additional information with reference to the functional capacity of the heart. While we were concerned with the condition of the heart and circulation, the study and observation of the changes in form, rhythm, murmurs, etc., our chief study has been that of functional response. It is interesting to note that the type of lesion, the valve involved, or the size of the heart, did not seem to have any definite relation to the exercise tolerance. Frequently children with chronic heart disease and fairly marked hypertrophy have shown a greater exercise tolerance than those with lesions of shorter duration and less hypertrophy. In our recommendation for physical activity of any kind, dyspnoea, rapid or irregular pulse, signs of lung congestion or cardiac asthma, and general muscular weakness, have determined our advice for prohibited or diminished exercise.

Many children who should carry on regular physical activity are prevented from doing so by overzealous parents. These children, who have been restricted in their activities because of the ignorance and over-sympathetic attitude of their parents, have developed a mental state which one might term an "exercise phobia"—a fear of exercise. This obsession has been overcome by examining this type of child in groups, in which are present children who are not so affected. The results have been startling and many of these cases that have suffered from this inertia for many months soon overcame it by the suggestion of "group example." There is no doubt that fear causes a diminution in morale among these children and that as soon as we make them understand that their condition is not hopeless, they become useful to themselves and of less concern and trouble to their parents.

Our roster during the past few years shows that we have had under observation and treatment about 950 children with between 70 and 80 new cases each year. With the establishment of

additional cardiac clinics in other institutions in the County during the past few years, many of the children were transferred to their own districts, many were also referred to their own physicians, and thus our case load was reduced to about 300 cases,—a comfortable and reasonable figure—to work with.

At present we have under observation and treatment 191 children with Mitral Insufficiency, Class I and IIA, 62 with Mitral Insufficiency and Stenosis, Class IIA and IIB, 16 with Mitral Stenosis, Class I and IIA, 8 with Mitral and Aortic Insufficiency, Class IIA and IIB, 18 congenital cardiacs in Class IIA, IIB and III, in addition to about 150 potential cases which are followed up in the Pediatric Clinic. Of the original number of these cases examined and classified in the past few years, 86 were transferred to other institutions in their district, 49 were discharged because of lack of cooperation, 12 died, and 116 were referred back to their own physicians. A goodly proportion of those in Class IIB were transferred to Class IIA, and those in Class IIA to Class I, after having shown sufficient improvement to warrant it. About 10% have been discharged while in Class I, after being observed for several years,—they having demonstrated such progressive improvement that they were able to carry on all the physical activities of the normal child.

As to the etiology in these cases, 189 were due to rheumatism, 68 to various infectious diseases, e.g., scarlet, pertussis and pneumonia, 18 were congenital, and 22 of unknown origin. With reference to incidence of rheumatic heart disease in these families, I reviewed the histories of 600 cases and found that there were 43 secondary cases, i.e., in 43 families two or more members of the family were suffering from an organic heart lesion due to rheumatism.

As to medication, it is our custom to use Salicylates only in cases of acute exacerbation, tonsillitis, growing pains and arthritis, and Digitalis in cases of fibrillation and tachycardia, and then with caution since many children do not stand it very well. Codein and Bromides were also used especially when pains and restlessness were persistent and continuous.

Social service contact has been of tremendous aid to these children as well as to their families. But despite the gratifying results much more could be done if this type of child was under more complete supervision. We can control and manage these children while they are ill at the hospital with some intercurrent condition or an acute exacerbation of their chronic condition or at the convalescent homes. But it is very difficult to control them in the intervals when they are at home. These periods are the most important from the standpoint of prevention of intercurrent conditions and extension of the lesions present.

We should have to begin a system of re-education with the parents—to teach them the art of protecting these lives which have been entrusted to them by nature. Many of them, surely, have not the mentality necessary to satisfactorily handle this home problem.

Most of these cardiopathic children are very sensitive and nervous. A good deal of this condition results from the lack of proper mental background. Where there are many children in the family, the others who are not ill, are not very considerate of the feelings of the cardiac, whom they consider as a cripple—as a useless member of the family, even though he be kin. Where the cardiac is the only child in the family, the oversympathetic attitude and overzealousness of the parents frequently harms the child. Peace in the household produces harmony, and discord produces nervousness in the child. Many parents think that they give all to these children when they give them food and air, but while food and air are enough for the body, the mental hygiene of these children should not be neglected.

We are frequently asked to designate the kind of work a cardiac should do, after graduation from school. This is a most difficult task and requires further study of the child's aptitude in different directions, taking into consideration his physical limitations. Many of these children come from poor families and are very ambitious despite their physical handicap, and in their zeal to help better the economic condition of their families, forget the physical limitations of their hearts. In the past few years we have been very fortunate in having the aid and cooperation of two great agencies,—the Vocational Guidance Bureau and the Cardiac Workshop—in properly advising and placing these unfortunate children. Many of these children have done splendidly under the supervision of these Bureaus, as evidenced by their condition at periodic visits to our clinic. It seems that the occupation to which they were assigned had no deleterious effect on their physical condition. Indeed, many who had had frequent exacerbations prior to their employment, rarely got them afterwards. It was interesting also, to note the change in their outlook upon life. Many had been led to believe that their condition would prevent them from doing any sort of work at any time. In many, in fact in

most instances, the disposition changed from a nervous, sensitive, heart-conscious and melancholy child to that of the happy care-free and almost normal child.

In conclusion, I desire to say that while the management of the cardiopathic child in this clinic for the past ten years has been a most difficult problem, it has been made extremely pleasant and interesting by the efficient aid of our Social Service Department under the leadership of Miss E. Fonaroff and her two able assistants, Miss I. Margoles and Miss B. Stoffberg, and by the wonderful aid, cooperation and loyalty of my colleagues, Drs. I. K. Mirkin and Leo. Rubin.

SUMMARY

1. The cardiopathic child is a type that requires special attention, study and supervision.
2. Employment of measures to improve the general health and eliminating all foci of infection, especially in the upper respiratory tract, tends to protect the heart from further damage, prevents recurrent infections and aids in the progressive improvement of the child.
3. Too much restriction on some children converts them into neuropaths and encourages a low morale, and too little restriction on others tends to further extension of the lesion present and increases the tendency to frequent exacerbations.
4. In comparison to the manner in which we treated these cases prior to the advent of a better understanding of this type of child, we now give them a better chance in life and a better outlook through attempt at regulation and management of their lives.
5. However, a more thorough, effective and ideal control and management of them can only be possible through the establishment of a Cardiac Colony—including a school—where the daily routine of these children can be observed and an intensive study of the child, his habits, characteristics, temperament and physical condition properly evaluated. The investment would be sound and the result,—a community of self-sustaining and healthier children, as a dividend,—and from the standpoint of preventive medicine, an opportunity to formulate proper and definite rules of prophylaxis, by co-relating all the facts and thus reducing the incidence of rheumatism among children.

DILATATION AND ITS INTERPRETATION*

By PAUL T. HARPER, M.D., ALBANY, N. Y.

It is with some hesitancy that there is
 ted for your consideration as com-
 topic as Dilatation. Than

condition of the cervix, there is no procedure with which the profession in general is more familiar; and there is none about which there has been more oral or written discussion.

The items to be elicited through examination are prescribed, and there are no new ones

to be added. But just how valuable the information so gained will prove to be, depends upon the use to which it is put.

For, after all, clinical proficiency is quite wholly dependent upon an analytical attitude toward all that is seen (and felt), and upon the ability to isolate fundamentals and make logical deductions therefrom rather than upon mere dexterity in carrying out the details of various therapeutic measures and operative procedures.

What follows is simply an account of individual reaction to the problem of the dilating cervix and what it tells about the probable termination of physiologically advancing labor on one hand and attendant pathological conditions on the other.

To illustrate. Balancing the dilatation found in a moderately well advanced first stage against an evaluation of the work being done by the uterus (in terms of frequency, length and strength of the contractions), one should be able to fix the hour of probable delivery with fair accuracy. The practical value of such information is at once apparent.

Again, with failure in progressive dilatation of a fully dilatable cervix in the presence of what appears to be wholly adequate contraction (it is presumed that two careful examinations have been made a matter of three or four hours apart), one is confronted with positive evidence of dystocia.

The abnormality may be one of muscular insufficiency or one of definite obstruction to advance. But, in either event, the diagnosis cannot be made too early.

Briefly set down, the various signs referable to the cervix that are to be considered are:

- 1 Length of the cervix, and length and general direction of the cervical canal (or what remains of it).

- 2 State of the internal os in terms of its gradual drawing up into and its leveling off with the musculature of the lower segment. Whether this process of elimination of the internal os is termed "obliteration" or "effacement" is immaterial.

- 3 Actual dilatation of the external os in terms of its diameter in centimeters or finger breadths.

- 4 Thickness of the cervix and lower segment (after the internal os has disappeared).

- 5 Consistence of the cervix (and lower segment) determined by palpation between the two examining fingers.

- 6 Presence of adhesions between the chorion and the decidual remnants in the lower uterine segment.

- 7 Location of the cervix as to its pelvic level as well as along the antero-posterior diameter of the pelvic cavity.

While, with examination early in labor, it would be impossible to elicit some of the signs referred to, they are all available after only moderately advanced dilatation, and, with the habit of such routine checking up acquired, the investigations can be carried out with surprising rapidity. It is at once apparent that there is much more to "dilatation" than determination of the size of the opening at the lower pole of the parturient uterus.

In what has gone before there has been no reference to information as to location of fontanelles and sutures to be palpated through the dilating cervix, and thus for the excellent reason that little if any information relative thereto is available *early* in labor, while during its *latter* part, developing caput not infrequently masks the so-called "diagnostic" sutures that the examining finger should feel.

This is especially true of the case where, in the presence of lack of progressive late first or second stage advance, one desires to differentiate between Bregma and Vertex Presentations or, on the other hand, where one wants to satisfy himself that he is dealing with an occiput posterior.

In either case, the abdominal signs are far more dependable and more easily elicited than are the vaginal.

To make practical use of the various cervical signs already referred to, each may well be considered in detail. There is scarcely one that does not present something of diagnostic, or prognostic, or therapeutic value. A few of them may be said to be pathognomic.

A Length of Cervix. The distance from the external os of a non-angulated cervix to the hemispherical lower segment offers positive information as to cervical and lower segment preparation for labor. A short cervix (1 to 1½ cms for instance) is one wherein considerable drawing upward of lower segment muscle fibres into the active uterus has already occurred and such a cervix, if primiparous, is one wherein the internal os is well along toward obliteration, and one wherein dilatation would be expected to advance satisfactorily in the presence of physiological contractions.

Such a cervix, if multiparous, can be counted upon to dilate speedily once efficient contractions are instituted. In the latter instance, the internal os has not disappeared. It and the external os commonly dilate together in multiparous labor, but the lower segment is thin. A short cervix alone in either case indicates thinning out of the lower segment (and preparation for satisfactory dilatation) even though in neither is the external os dilated sufficiently to investigate the actual thickness of the lower segment or the state of the internal os.

The practical value of a short, non-angulated cervix arises in the occasional case of accidental hemorrhage or rapidly advancing toxæmia where decision between delivery by Section and delivery by the vaginal route must be made. A short cervix offers considerable latitude in artificial dilatation therapy whereas, in the presence of a long, thick (unchanged) cervix and the necessity for reasonable haste, the risks of abdominal section might have to be unhesitatingly assumed.

Length and general direction of the cervical canal can rarely be determined directly because the mere fact that the canal persists, precludes the possibility of sufficient dilatation of the external os for the examining finger to enter it.

However, angulation of the cervix, particularly if the latter is short, invariably indicates persistence of the canal. Angulation is usually forward (for uterine ante flexion is normal) and the canal accordingly directed backward; but length of the canal and, in addition, obliteration of the internal os are measured indirectly by evaluating the length of the cervix presenting. Obviously, the shorter the cervix, the thinner the lower segment. The thinner the lower segment, the shorter the canal and the more satisfactory is the preparation of the cervix for dilatation.

Angulated cervixes are in no sense pathological. They are met where engagement is firm. Angulation results from the push of the engaged head down against the cervix, that is more or less fixed by its ligamentous supports.

B. Obliteration or Effacement of the Internal Os.

This is the cardinal step in the dilatation of the primiparous cervix.

In response to contractions (either preliminary or those of actual labor), two mechanical forces become active. They are (1) the downward and outward "push" of the intact bag of waters and (2) the outward and upward "pull" of the longitudinal active uterine-muscle fibres. Their joint effect is gradual upward displacement of cervical and lower segment muscle fibres with obliteration, or widening up, or fading away of the internal os into the progressively thinning lower segment.

There is actual displacement of muscle fibres. Before obliteration of the internal os, the lower segment near the cervix may present a thickness of 2 cm. or more. Whereas, with the internal os entirely obliterated, its thinness may be down to $\frac{1}{2}$ cm.; and it is uniform. This is most important. A cervix may present an external os that will readily admit the examining fingers and that is paper-thin; but if progressive thickening of the lower segment is encountered as the region of the fading internal os is approached, the latter is not "ob-

literated" and the cervix is not ready for progressive dilatation, be the latter spontaneous or artificial.

Cases of the kind can be gotten up to "3 or 4 fingers" under digital dilatation and anaesthesia, but no further. And when artificial advance through them is attempted, they tear extensively if moderately thinned and excessive force is used, or they hold, the lower segment acquiring defensive "tone," and foetal and maternal mortality and morbidity rates rise with the increased trauma incident to operative delivery.

Uterine muscle dystocia of the type referred to is far more important clinically, because more common and more dangerous, than is the obstruction occasioned by pelvic contraction alone.

As long as a trace of unobliterated internal os remains, advance and delivery of a full-term child may not be attempted operatively. The "size" of the forecoming head with forceps applied is inevitably increased by the thickness of the surrounding lower segment musculature; while extended arms and delay in delivery of the aftercoming head are the usual hazards in delivery by the breech.

Even though the patient has entered upon a clinical second stage with frequent, strong and actually propulsive contractions, the abnormality may not be allowed to go untreated: Contractions must be decreased to the frequency and intensity that the anatomical dilatation calls for. This means anaesthesia and, preferably, ether in olive oil by rectum. The dose should be large (4 ozs. for instance) and its efficiency in decreasing the frequency and intensity of the contractions down to the point of safety for the child alone should be considered in repeating it. The foetal hazards arising from the ether instillation are much less than those of long continued spontaneous efforts at expulsion though a non-fully-dilated, or -dilatable, cervix. They are negligible compared with those of operative interference under the same conditions.

On the other hand, with the internal os wholly obliterated and the lower segment uniformly thin, a case is deliverable (granted an emergency demands it) regardless of the dilatation of the external os.

Under deep ether anaesthesia, a primiparous cervix with the external os dilated no more than one finger, but with the internal os wholly obliterated, can be brought to full dilatation within twenty minutes and be found intact on careful post-partum examination.

Full digital dilatation of a completely prepared cervix and immediate delivery by forceps, or "version," or breech extraction, depending upon conditions as to presentation,

level of the presenting-part and the like, becomes a highly valuable therapeutic measure applicable to an extremely limited number of cases but possessed of advantages in these cases that far exceed those of expectancy.

Scant reference need be made to behavior of the internal os in dilatation of the multiparous cervix. Even before labor this cervix presents a variable degree of dilatation of the external os while the internal remains discrete, firm, and more or less tightly closed. So it remains until very late in, or throughout, labor. Internal os and external os gradually approach each other as the cervical canal grows progressively shorter with progressive thinning out of the lower segment.

It is the latter that makes relatively rapid dilatation of the multiparous cervix possible. At the same time, it is the relatively thick margin of the dilating multiparous cervix, together with descent resulting from lax pelvic floor and broad ligaments, that accounts for a common element of dystocia met late in labor and to which reference will presently be made.

C Dilatation of the External Os

This is the familiar sign, and centimeters, inches and fingers' breadths are the various standards by which it is measured. It is the simplest one to elicit, and it can be made out with approximate accuracy in the majority of instances by rectal examination. But, in itself, it is possibly the least valuable from a prognostic standpoint.

For example a primipara, external os "2½ fingers", contractions recurring every three minutes (20 to the hour) and lasting thirty seconds (10 min of dilatation to the hour), condition of the internal os and thickness of the lower segment undetermined. (As a matter of fact, a remnant of internal os persists and the lower segment increases to 1½ cm in thickness as the region of the latter is approached.) A physiological second stage need not be looked for in hours, while the time of actual delivery is even more problematical.

On the other hand, with the same "2½ fingers" but with the lower segment thin and possessed of no "tone," with the cervical rim soft between contractions, labor is advancing rapidly and with even a slight shortening of the intervals between contractions and a slight increase in their intensity and duration, onset of the second stage and delivery can be looked for within a very few hours.

D E. Thickness and Consistency of the External Os and the Lower Segment

Theoretically, the margin of the external os is reduced to paper thinness in preparation for uneventful dilatation, and the lower segment increases very gradually in its thickness as higher levels are reached. With the internal

os completely obliterated, there is no trace of it to be palpated as its original level is reached.

And the musculature of the external os and the lower segment, although its feel is definitely firm at the height of uterine contractions is invariably soft in the intervals between them. This characteristic is essential. None but a contraction applied to a soft and relaxed cervix results in maximum dilatation.

On the other hand, a feeling of firmness to the cervical musculature in the intervals between contractions is indicative of a persistence of muscle "tone" that not only retards progressive dilatation but, if sufficiently pronounced, may even put a stop to it altogether.

Cervical and lower segment "tone" between contractions is not uncommon where with membranes ruptured and contractions frequent, strong and prolonged, the entire uterine musculature applies itself to the irregularities of the foetal outline in what is aptly termed a state of general uterine retraction.

These cases need treatment, and the latter is sedative. Morphine in the first stage and rectal ether in the second are specifics. Attempt to dilate these firm—possibly "rigid"—cervices digitally may not be made. Their dilatation without anesthesia is dangerous, while, with sufficiently deep narcosis or rectal anesthesia and time, they can be counted upon to open spontaneously.

F Lower Segment Adhesions

They are the sequelae of antecedent productive inflammatory processes in the cervical and lower segment mucosa. Patients presenting them give histories of leukorrhoea and variable dysmenorrhoea.

When present, lower segment adhesions invariably retard dilatation. If definitely obstructive, they must be eliminated if labor would not be unduly prolonged.

Adhesions "hold" even in the presence of frequent, strong and highly efficient contractions for the reason that the "pull" upon them to break them up is lateral and, therefore, mechanically ineffectual.

In an interval between contractions a finger is introduced through the external os and swung completely around as much of the lower segment as can be reached. The adhesions are felt to give way in response to little force and their breaking up is accompanied by a moderate muco sanguinous "show" throughout which minute yellowish flakes are scattered.

Search for the presence of obstructing adhesions is indicated whenever a thin, soft, and apparently readily dilatable cervix fails to progress in its dilatation in the presence of highly efficient contractions.

G Location of the Cervix

Pelvic level at which the cervix is found is

determined by the degree of engagement and descent of the presenting-part. Dilatation in a "low" cervix can be counted upon to proceed with maximum speed for the simple reason that there is, in contact with it, a firm, uniformly rounded presenting-part out and up over which the lower segment can be directed with maximum ease.

Location of the cervix along the antero-posterior pelvic axis is of diagnostic as well as prognostic importance. In every *occiput-posterior*, the cervix is located well toward the rear. Such displacement is an attempt at accommodation of the long axis of the uterus, terminating inferiorly at the cervix, to the long axis of the presenting-part—the occipito-mental diameter of the foetal head—that is directed generally toward the rear.

While less valuable than the abdominal signs that are characteristic, the fact that the cervix is located posteriorly and remains well to the rear until late in dilatation should suggest a "posterior," with its attendant possibilities as to clinical course, even though on palpation and auscultation the case has been considered an "anterior."

Reference has already been made to the fact that some cervical signs are pathognomonic. There are few; but their importance lies in the fact that they indicate conditions that, on one hand, are not uncommon and that, on the other, demand early diagnosis. Early diagnosis is emphasized because, when made, treatment is at once simpler and more availing.

These conditions belong among the uterine dystocias. They are (1) uterine muscle insufficiency, (2) general uterine retraction, and (3) ring obstruction. On cervical exploration alone positive diagnosis of these abnormalities can almost invariably be made.

(1) A soft, thin, moderately dilated cervix, presenting a negligible advance in dilatation over a period of two or three hours of apparently highly efficient contractions, means uterine muscle insufficiency, or disproportion, or (as is usual) a combination of the two.

"Insufficiency" is used in preference to "inertia." The former term indicates that the contractions are simply inadequate to bring about progressive advance in dilatation. They are insufficient, but the musculature is far from inert. As a matter of fact the contractions may be unusually strong. But, regardless of their strength, when they are producing negligible results in progressive dilatation during the first stage and in advance of the presenting-part in the second, they are insufficient: help is needed: and care must be exercised lest it be too long deferred.

The insufficiency just described is Relative, and the earlier in labor it appears the less

promising is the outlook. Unrecognized and untreated, relative uterine muscle insufficiency results in true inertia, with its necessarily increased tractile efforts at delivery and its even *more serious* increased post-partum blood loss.

No less important than the diagnosis of relative insufficiency (or relative inertia) is its treatment. The latter may never be stimulative. Pituitary extract takes from rather than adds to the store of uterine-muscle energy available. Accordingly, a uterus that has already given evidence of being unequal to the work at hand may not be called upon to work harder.

The indication here is to lighten the uterine load; and careful digital dilatation in the first stage and conservative forceps extraction in the second (supplementing the still-present uterine contractile efforts) are the measures to be employed.

(2) A firm cervix, in intimate contact with a sizable caput (the membranes have almost invariably ruptured in cases of the kind) and maintaining its "tone" even in the intervals between subjective "pains," strongly suggests general uterine retraction. The diagnosis becomes positive when, on abdominal examination, the various prominences, depressions and deep furrows of the foetal outline stand out as the uterine muscle applies itself intimately to the foetus; and the entire uterine musculature imparts the same sensation of "tone" to the palpating hand that it conveys to the vaginal finger.

Treatment here is empirical. The uterine musculature must be relaxed, and intermittency made to return to the contractile efforts. Depending upon the amount of relaxation to be produced, use is made of chloral and bromide, or morphine with atropine, or rectal anaesthesia, or, in the extreme case, deep surgical ether inhalation possibly over a period of twenty or thirty minutes.

Most moderately well dilated but "rigid" cervixes are found in cases of advanced general uterine retraction. None may be dilated digitally as they are; but practically all go on to complete physiological dilatation when the sedative treatment described is started early enough or persisted in long enough.

(3) Recession of the presenting-part from contact with the rim of a previously dilating cervix, accompanied by cessation in dilatation of the external os, means the activity of some force just in advance of the bis-acromial foetal diameter. Bandl's Ring in tonic, isolated contraction gives just such signs early in its development. Recession as described demands immediate lower segment exploration under deep ether to determine the possible presence of a developing Ring.

If found (and when fully developed it will encircle the neck), the treatment is continuous anaesthesia until the Ring has disappeared. No attempt need be made to dilate it manually. With the Ring eliminated, immediate delivery following complete manual dilatation of the cervix is called for.

In cases of the kind, as well as in those of general uterine retraction, the dangers of pituitary extract medication need only to be mentioned to be thoroughly appreciated.

The following findings are not uncommon in multiparous labor. Presenting part in the low mid pelvis; contractions frequent and strong although poorly propulsive; rim of the cervix out of reach at the sides and posteriorly but a conspicuous anterior lip behind the symphysis and anterior to the head.

The anterior lip, characteristically somewhat elongated in multiparae and remaining somewhat thickened during dilatation because the internal os and the external dilate together, has become incarcerated between the firm head and the firmer symphysis. Relaxed pelvic floor and broad ligaments allow of the deep descent necessary for such incarceration.

The thick lip is a definite obstruction to advance, and it rises slowly if at all. Yet propulsive efforts be encouraged and its thickness increases. The incarcerated cervix readily becomes oedematous, and the moment of spontaneous delivery is further and further deferred.

A simple measure here is universally successful. The tips of two or three fingers displace the incarcerated anterior lip upward above the symphysis and hold it there until an efficient contraction appears. At this time, carefully withdraw the fingers, and the presenting part—its obstruction to advance removed—will be found to be delivered with surprising ease.

This procedure is so simple, so safe and promises so to minimize wear and tear on patient and those about her that it ranks as one of the most valuable of therapeutic measures.

Reference has been made earlier in the discussion to analysis of contractions as to frequency, intensity and duration for the purpose of measuring the amount of work in dilatation the uterus is doing.

Work being done can be measured. For instance, with contraction recurring at 3 min intervals, there are 20 such efforts within an hour. With each contractile effort lasting 45 seconds ($\frac{3}{4}$ of a minute), it is at once apparent that the uterus is devoting 15 minutes of each hour to dilatation. Fairly rapid dilatation would be expected.

But other factors are to be considered. They are, first, the strength of each contractile effort and, second, the condition of the cervix (its dilatability) at the time the observation is made.

Accurate measure of the strength of the contractions may be impossible, but they are manifestly mild, or moderate, or strong and an approximate evaluation of them can be made. But more definite is the information the cervix offers. With the latter thin and soft with the internal os obliterated and the external dilated three fingers for instance one can determine with fair accuracy how much more work will be necessary to bring about full dilatation. Analysis of the contractions in the manner already described offers evidence of the work the uterus is doing and the latter may be expected to be increased as the late first stage is entered upon. One should have little difficulty in fixing with approximate accuracy the hour of actual delivery.

In conclusion, a few words concerning the place of vaginal examination in the conduct of labor are not amiss.

There are those who look upon each vaginal as involving definite hazards, and who urge the substitution of rectal examination as an effective means of eliminating them. Enthusiasts claim that vaginal examination is never necessary.

Even if the various items of interest referable to cervix and lower segment could be elicited on rectal examination, vaginal exploration during labor would still have a place if for no other reason than that it is only as a result of such a procedure that artificial rupture of membranes is possible. And the indication to rupture the membranes is on occasion imperative.

But none of the finer points of cervical anatomy and physiology are demonstrable through rectal examination alone, and vaginal examination unquestionably has a place in practice.

Vaginal examination may not be eliminated. It may not be relegated even to a position of secondary importance to rectal.

Unless the case is progressing too rapidly, each parturient is entitled to a carefully conducted vaginal examination. In the interest of safety make use of rectals to check up on the subsequent progress in labor.

The latter course is not only conservative. It is informative as well. When followed none will be subjected to the acknowledged hazards of vaginal examination without definite benefits therefrom, and such advantages are possible in no other way.

THE MEDICAL PRACTICE ACT—FIVE YEARS' RESULTS

By HAROLD RYPINS, M.D., ALBANY, N. Y.

Dr. Rypins is Secretary of the State Board of Medical Examiners, and the Executive Secretary of the Grievance Committee, New York State Department of Education.

ALTHOUGH the Webb-Loomis Bill became a law by Governor Smith's signature on November 17, 1926, the effective machinery for putting its provisions into practical operation were not fully organized until January of 1927. It should be of interest to the medical profession, who not only sponsored this legislation, but who are carrying its financial burden, to know what has been accomplished during the first five years of its actual operation.

At the time this legislation was proposed, five questions were asked in regard to it:

1. Was there any necessity for amending the Medical Practice Act?
2. If so, would the amended Act remedy the evils for which it was intended?
3. Would the benefits to the public and the medical profession be sufficient to justify the burden imposed on the medical profession?
4. Would the Act in any way jeopardize the rights of licensed practitioners of medicine?
5. Would a temporary or permanent activity be necessary?

With the completion of a five-year period of administering the Medical Practice Act, I believe I have accumulated sufficient experience and data to answer these five questions definitely and satisfactorily.

WHAT THE MEDICAL PRACTICE ACT PROPOSED

There were two major objects in amending the Medical Practice Act in 1926—first, to drive out of practice unlicensed quacks and charlatans; and second, to remove from medical practice licensed physicians guilty of improper professional conduct. To accomplish these results several things were necessary. First, it was necessary to know who was and who was not actually entitled at any given time to practice medicine in the State of New York. This required annual registration. Second, it was necessary to clarify and strengthen the penalty clauses; third, it was necessary to prohibit the unauthorized use of the title "Dr."; fourth, it was necessary to transfer legal prosecutions from the local district attorneys to the office of the Attorney General; fifth, it was necessary to establish an administrative bureau with sufficient inspectors and investigators; sixth, it was necessary to create the Grievance Committee and set up a legal procedure for its activities; and seventh, it was necessary to secure sufficient funds free from political interference to carry out the purposes of the act. This called for the annual two dollar registration fee.

The following table gives the disposition of cases of illegal practice of medicine, received during the year 1931, and also a summary of all similar cases disposed of during the five-year period, 1927-31:

RESULTS OF PROSECUTION OF ILLEGAL PRACTITIONERS		
Classification	1931	Total 1927-1931
No Cause for Action ...	131	1066
Violations Stopped		
Without Prosecution	197	1355
Prosecutions	62	274
Convictions	43	205
Acquittals	7	19
Withdrawn	5	43
Pending trial	7	7
Investigations Incomplete	237	237
Total	627	2,932

SUMMARY

No evidence of violation	1,066
Outcome satisfactory	1,560
Outcome not satisfactory	62
Incomplete	244
	<hr/> 2,932

Attention is called to the fact that during the five-year period 2,932 complaints of illegal practice have been investigated, of which 1,066, or a little over one-third, showed no violation. One thousand, eight hundred and sixty-six violations of the statute were found, of which 1,355 were stopped without the necessity of criminal prosecution. Two hundred and thirty-seven cases are uncompleted and 274 were prosecuted in the criminal courts.

Of the 274 prosecutions, 205 were convicted, 19 acquitted, 43 withdrawn and 7 are pending in the courts. Over ninety per cent of actual convictions were obtained in the cases brought to criminal trial, which is a phenomenally high record in criminal prosecutions. Particular appreciation is due the Honorable John J. Bennett, Jr., Attorney General of the State of New York, and the very able deputy attorneys general, the Honorable Sol Ullman and the Honorable Myron J. Parkinson, assigned to the prosecution of these cases, for their very great zeal and co-operation in the enforcement of the statute. The extensive experience which they have acquired in the prosecution of these cases is in no small measure responsible for their extraordinary success and testifies to the wisdom of centralizing these prosecutions in the hands of the Attorney General. The district attorneys, particularly in

New York City, have also been most helpful in cooperating with the Attorney General

The effectiveness of the Medical Practice Act, however, cannot be seen solely in the figures of criminal prosecutions, but is better shown under the caption "Violations Stopped Without Prosecution" This group is composed of minor or technical violations Frequently, the unauthorized display of the title "Dr" and similar violations are as a rule now easily stopped by a warning visit from one of the inspectors of the Department It is obvious that this is a simpler procedure than criminal prosecution, requiring a much smaller expenditure of time, energy and money The fact that these violators do not require being brought into court to stop their violations is in a large measure due to the public recognition of the effectiveness of our criminal prosecutions It is generally appreciated that the State has both the intention of and the machinery for prohibiting violations of the Medical Practice Act, that the chances of a violator in the criminal courts are very poor and the penalties severe, ranging from fines up to five hundred dollars and jail sentences up to a year, or both In other words, it has become known that the illegal practice of medicine is no longer a paying "racket"

Another type of evidence that the Medical Practice is accomplishing its object is difficult for anyone not intimately acquainted with the administration of the law to appreciate, that is, a very definite change in the character of complaints over the five-year period For the first few years a majority of the complaints received involved flagrant and serious violations, consisting of the out-and-out diagnosis and treatment of the sick without restriction, by unlicensed practitioners This type of case has been gradually diminishing, so that the majority of complaints at the present time are of a lesser and more technical nature, such as the use of ultra-violet ray in beauty shops, or the use of the title of "Dr" by licensed massage operators, chiroprodists and optometrists, who are otherwise engaged in legal practice The outright practice of medicine in open defiance of the State authorities has diminished tremendously over a period of five years, whereas, owing to the education of the public, the number of technical violations which, if not promptly stopped, would doubtless lead to more serious violations, has tended to increase The total number of cases investigated annually remains at approximately 600, though the character of these violations has definitely altered for the better

In particular, the unauthorized use of the title "Dr" by unlicensed cultists, which more than any one violation misleads and deceives the public, has now practically disappeared and its effectual prohibition has been a body blow to practitioners of the various cults

An amusing light on the effect of the enforcement of the Medical Practice Act upon cultists is contained in the reports of the Department's investigators, who state that on numerous occasions they are confronted with their own photographs, by unlicensed cultists who are in constant fear of detection Thus fear has led them to insist upon so much evidence that new patients are not inspectors that their caution has driven away most of their new patients, who naturally do not desire treatment when the practitioner not only by his actions but by his words is forced to tell them that what he may do is in violation of the law

Although it has naturally been impossible to obtain any accurate data as to the actual number of illegal practitioners in the State at any given time, all these lines of information lead me to feel justified in concluding that, speaking very conservatively, the number of illegal practitioners of medicine in New York State has been cut more than in half during these five years, and that their number is decreasing duly A comparison of the practitioner's signs displayed now as contrasted to those of five years ago fully bears out this conclusion A comparison of the present practitioners' signs with those displayed in other states will satisfy the most sceptical that illegal medical practice is under better control in New York State than anywhere else in the country, a fact testified to by no less competent a judge than Dr Morris Fishbein, Editor of the *Journal of the American Medical Association*

THE WORK OF THE GRIEVANCE COMMITTEE

The second major object of the amended Medical Practice Act was the creation of a Grievance Committee for the purpose of reprimanding, suspending, or revoking the licenses of physicians guilty of improper conduct The Grievance Committee, of which Dr Orrin Sage Wightman is the very able chairman, is composed of ten physicians, appointed by the Board of Regents from nominations of the various state medical societies The members of the Grievance Committee serve without remuneration and they have given unstintingly of their time and energy in carrying out the work of the Committee

While the original object for which the Grievance Committee was proposed has been accomplished, namely, the discipline of physicians guilty of improper conduct, the Grievance Committee also serves two other very useful purposes It has served as a court where unfounded charges against licensed physicians are heard and disposed of without the publicity and expense of the usual court procedure Perhaps even more important, the general recognition of the Grievance Committee's existence, functions, power and determination, has undoubtedly operated as a deterrent to licensed physicians whose mode of practice

borders on the questionable, so that the Committee has had a very definite effect in raising the standards of professional conduct throughout the State.

During the four years of its existence, the Grievance Committee has received 201 complaints against licensed physicians. The type of these complaints and the manner in which they were handled is shown in the following table:

COMPLAINTS AGAINST LICENSED PHYSICIANS

Sept. 1928—Jan. 1932

Complaints	Violation	Disposed of by						Regents Action	
		Secretary	Informal hearing	Formal hearing	Revocation	Suspension	Censure	Dismissed	Pending
36	Improper Advertising	18	16						1
30	Attempted Abortion	10	9	1	2	1			7
36	Aiding Illegal Practitioners	10	13	1	2	1	4		5
16	Ambulance Chasing		14	2					
25	Fraud and Deceit	6	11		2		1	1	4
18	Malpractice	11	7						
11	Unethical Conduct	4	7						
1	Narcotic Violation				1				
1	Insanity				1				
1	Arbitration		1						
26	Miscellaneous	17	7						2
		76	85	4	8	2	6	1	
201	Total		165			17			19

Reference to the table shows that of these 201 cases, 76 were disposed of by the Executive Secretary on the grounds that there was no evidence of a violation, or that the charge did not fall within the purview of the Committee, under the statute—for example, charges of malpractice. These 76 cases, together with the cases in which after informal hearing by the sub-committee, the physician complained about was exonerated, make a group of 100 cases, just one-half of all the charges received, in which the physician improperly charged with misconduct was protected by the Grievance Committee. So far as can be ascertained, not one of these cases has ever appeared in a civil court, indicating that not only the complainants but their legal counsel are satisfied that the determination of the Committee is fair and unprejudiced. These complaints seek a place to air their grievances. They appear to be satisfied, after an opportunity has been given them for a courteous hearing, to accept the Committee's decision in the matter. Before the existence of the Grievance Committee these cases usually found their way to the courts, where the physician, even though perfectly innocent of wrong-doing, was subjected to very embarrassing publicity and expense. From the point of view of the medical profession the protection afforded by the Grievance Committee to these one hun-

dred physicians of itself justifies the cost of the Medical Practice Act to the medical profession.

The remaining 101 cases against licensed physicians, on the other hand, constitute cases in which there was definite evidence of wrong-doing to a greater or lesser degree, and the Committee has been just as zealous in these cases in protecting the injured public as it was in the other cases in protecting the injured physician. Of the 84 cases heard informally, I have already indicated that in 24 cases the physician had acted properly. Subtracting the 19 cases which are still pending, and 17 cases referred to the Board of Regents for formal discipline, there were 41 cases in which the evidence indicated improper conduct on the part of the physician, but of a nature not justifying formal discipline. In these cases the physicians were warned by the Committee and advised that should they be brought before the Committee again the earlier charges would be reopened. The same action was taken in 4 cases after the hearing of formal charges, where insufficient evidence to justify reference to the Board of Regents was found, but the Committee was convinced that the physicians had not acted properly. Only 2 of these physicians have been called before the Grievance Committee a second time.

Of the 17 cases referred to the Board of Regents, 3 cases were for attempted abortion, of which 2 were revoked and 1 suspended; 7 were for aiding illegal practitioners, of which 2 were revoked, 1 suspended and 4 censured; 4 for fraud and deceit in practice, of which 2 were revoked, 1 censured and 1 was dismissed by the Board of Regents. One license was revoked for narcotic violation and another for insanity. With the exception of one case the Board of Regents has accepted the recommendation of the Grievance Committee; and the Appellate Division has sustained the Grievance Committee and the Board of Regents on appeal.

Experience has shown that the Grievance Committee can accomplish the greatest results by the use of informal hearings, and formal hearings are now held for the most part only in those cases in which after informal hearing the Committee is satisfied that the facts warrant severe discipline. The results accomplished by the Grievance Committee have attracted attention throughout the country and several states are now in the process of amending their medical practice acts to include similar disciplinary bodies.

SUMMARY

In conclusion, I believe that the data which has been presented is sufficient to answer the five questions which were raised in reference to amending the Medical Practice Act in 1926:

1. The number of cases of illegal practice found—almost 3,000 in five years, or approxi-

mately 600 a year, as well as the 200 complaints against licensed physicians, filed with the Grievance Committee—indicates that there was a necessity for amending the Medical Practice Act.

2. The results of the criminal prosecution of illegal practitioners and their steady diminution through the State, as well as the effect of the Grievance Committee, indicates that the Act, as amended, is remedying the evils for which it was proposed.

3. The benefit to the medical profession of the Grievance Committee as well as the profession's natural interest in the control of illegal practice for the benefit of the public they serve, is sufficient to justify the burden imposed on the medical profession for the Medical Practice Act.

4. During its five years of operation no single complaint has been received which would in any way indicate that any physician has felt that his rights have in any way been jeopardized.

5. The fact that after five years there is still an abundance of work to be done both in the prosecution of illegal practitioners and in the discipline of licensed practitioners indicates that a permanent and not a temporary activity along these lines is necessary.

It is my opinion that the results obtained during the first five years' operation of the present Medical Practice Act fully meet the expectations of its sponsors, and that New York State now possesses the model and most effective medical practice act of the country.

LUMBAR HERNIA WITH OVARIAN CYSTS

By JACOB SARNOFF, M.D., BROOKLYN, N. Y.

THE purpose of presenting this case report is to illustrate some unusual phases of post-operative hernias complicated by intra-abdominal growths. These growths aggravate the hernia but facilitate hernial closure after their removal because the intra-abdominal content is thereby diminished. Post-operative ventral hernias are quite frequent even to-day in spite of improved technique, because of the innumerable laparotomies performed, especially in the presence of suppuration. Problems of post-operative hernias are therefore familiar to the average surgeon. Lumbar hernias, however, are somewhat rare and as a rule are approached with greater timidity and caution.

The structures of the abdominal wall in the lumbar region are less yielding, the muscle layers having fixed points of attachment, and the underlying viscera being in close contact with them and partly extraperitoneal, such as the kidneys and colon. This region therefore, is less amenable as a surgical approach to the abdomen. Watson in his text book on Hernias has collected from the literature up to 1923, one hundred and fifteen cases of lumbar hernia out of which three were post-operative. The others were congenital or acquired, either emerging through the inferior lumbar triangle (Petit's) or superior lumbar triangle (lumbo costo abdominal triangle of Gryn-Felt.) He states that unquestionably there are many more post-operative lumbar hernias, but that a good many are not reported.

The most frequent incisions in the lumbar region are for kidney operations, such as nephrectomy, pyelotomy or ureterotomy. It is the result of such operations that a hernia sometimes develops, especially if there is a

good deal of suppuration. The structures of this region are: skin, a good layer of fat, three layers of muscle, namely, the latissimus dorsi going upwards and forwards, the external oblique going downwards and forwards, the internal oblique going upwards and forwards, the transversalis muscle going transversely across toward mid-line, transversalis fascia, preperitoneal fat and peritoneum; the erector spinae muscle posteriorly, the crest of ileum below, the twelfth rib above, and the linea semilunaris in front. The lower intercostal vessels and nerves pierce the various layers of muscle on their way downwards and forwards. During these operations these structures are at times severed. If the approximation is proper and union is primary no ill effects ensue, but if suppuration takes place, a defect may be produced which predisposes to hernia formation, especially when there is a tendency for the increase of intra-abdominal pressure such as this case illustrates.

A woman C. F. admitted to the United Israel-Zion Hospital, June 3, 1931, was 37 years of age, married 17 years, one child of 16, regular menstrual periods. Suffering from polyarthritis. Six years ago patient weighed 175 lbs. During the first three years patient complained of frequent micturition and lost 75 lbs. in weight. Was diagnosed as suffering from tuberculosis of left kidney for which nephrectomy was performed three years ago. The pathological report was caseous tuberculosis of left kidney. A good deal of suppuration with prolonged drainage continued for a number of months following the operation.

The patient sustained a severe injury to the left lumbar region by falling off a trolley car about a year following the nephrectomy.

Shortly after the injury, a swelling was noticed in the left lumbar region, at the site of the former operation, which progressively increased in size. When first noticed, the swelling was the size of a tangerine but it gradually increased until on admission it was the size of a watermelon. Her weight following the nephrectomy mounted from 100 lbs. to 234 lbs. which was her weight on admission to the hospital (Figures 1 and 2 left).

FIGURE 1

Left: Anterior view of lumbar hernia extending above from lower ribs, below to crest of ileum, behind to erector spinae, in front to linea semilunaris.

Right: Anterior view three weeks after operation, showing marked improvement in abdominal contour, general posture and facial expression.

The patient was first admitted on the Medical Service because she was suffering from polyarthrititis, having a temperature of 104°. After being in the hospital for ten days her condition improved and her temperature became normal. A surgical opinion was then requested as to the advisability of operating on the lumbar hernia. On examination the writer found the hernia partly irreducible, as it was impossible to force back the contents completely into the abdominal cavity. Such an attempt produced a great deal of distress, marked intra-abdominal tension, dyspnea, palpitation and a sense of suffocation. The hernial opening was large enough to admit two hands. Through this defect one could feel a tumor mass springing from the pelvis, suggestive of an ovarian cyst (Fig. 3).

Ordinarily the writer would feel that an attempt at reduction and closure of such an enormous hernia would prove futile for there would not be room enough in the abdominal cavity to accommodate the extruded viscera housed in the large hernial sac. This was the

opinion of his medical colleagues. However, anticipating the removal of the large tumor mass, the writer felt that reduction of the hernial contents would then become feasible. The mass undoubtedly was partly responsible for the gradual increase of the hernia and the displacement of the abdominal viscera into the hernial sac.

To insure the successful outcome, the patient was put on a non-residue diet, and subjected to thorough catharsis to minimize the intestinal volume. This, coupled with a marked relaxation of the abdominal wall produced by the spinal anæsthesia, enabled the writer to proceed with the operation without hesitancy. An elliptical incision two feet long and one foot wide was made in the left lumbar region excising a thinned out scar consisting of practically only skin and peritoneum which formed the major part of the hernial sac. To the inner surface of the sac was firmly adherent the large omentum, the descending colon and many coils of small intestine. These adhesions were probably the result of the former suppuration. The adhesions were separated and the redundant omentum removed. The entire circumference of the hernial ring together with the surrounding fascia and muscles were exposed. The hand was then introduced into abdominal cavity and a large twisted ovarian multilocular papillary cyst about the size of a watermelon was found springing from the left broad ligament, partly protruding through the hernial opening. The pedicle, about the thickness of two thumbs, was clamped and cyst removed. The pedicle was ligated with chromic No. 2.

Further exploration revealed a similar multilocular cyst of the left ovary, though much smaller. This was removed in the same manner. The writer was then able to close the defect without drainage and without any difficulty, ensuring proper and firm approximation of the different layers constituting the abdominal wall of the left lumbar region. The peritoneum and transversalis fascia were sutured with continuous chromic No. 1, the transversalis internal oblique and external oblique muscles were sutured with continuous chromic No. 2 in two separate layers. A few interrupted sutures were used to reinforce the line of approximation. Skin and fascia were sutured with interrupted silkworm figure 8 and the writer's continuous silk suture for skin.

On completion of the operation, the left side appeared quite even, symmetrical, and in fact had a better cosmetic effect than the right side. The entire procedure, requiring a good deal of tailoring, lasted forty-five minutes. Patient appeared to be in excellent condition following the operation. Had a smooth convales-

cence. Wound healed by primary union. Patient was up and about in two weeks and was discharged from the hospital as cured, in three weeks, a transformed individual both mentally and physically as evidenced by her facial expression and physical form. (Figs. 1 and 2 right).

The pathological report of both ovaries was that of multilocular papillary cyst-adenoma. The left cyst weighed nine and one half pounds and contained four and one half quarts of clear fluid. The patient now is thus minus one kidney, both tubes and ovaries, and yet at date of this writing, two months following the opera-

FIGURE 2

Left Posterior view of lumbar hernia
Right Posterior view three weeks after operation

tion, is in perfect health, despite her having been subjected to a nephrectomy for tuberculosis of the left kidney, bilateral salpingo-oophorectomy for papillary cyst adenoma of both ovaries and hernioplasty for the huge post-operative lumbar hernia. She now weighs 190 lbs, as compared to 234 lbs on the date of admission and therefore can get about with more ease and comfort.

The facts of this case bring to our mind the following:

1. Lumbar hernias are apt to result after

FIGURE 3

The left ovarian multilocular cyst weighing nine and one-half pounds, containing four and one-half quarts of clear fluid, with innumerable cysts on the surface and in the interior. The right ovary had a similar cyst but smaller.

nephrectomies, especially if there is a good deal of suppuration.

2 Intra-abdominal growths predispose to the formation of such hernias by causing increased intra-abdominal pressure, the weakest part of the abdominal wall yielding.

3 The problem of replacing huge hernias such as this one can be partly solved by thorough purgation, non-residue diet, aided by the marked relaxation obtained by spinal anaesthesia; and in cases of this type by the removal of non-desirable voluminous tenants in the form of ovarian cysts.

4. The intricate physiological and anatomical disturbances jointly, caused by the ovarian cysts and the lumbar hernia, have produced, in this particular case, marked dysfunction in the form of obesity, despondency and suffering. Following the operation (Fig. 1 right) there is a marked improvement in the patient's physiognomy as evidence by her expression of joy, alertness, vivacity and well being.

TWO CASES OF URINARY RETENTION FROM VAGINAL OCCLUSION

By JOSEPH A. LAZARUS, M.D., NEW YORK, N. Y.

ONE of the chief causes of occlusion of the vagina is a union of the epithelial surfaces of the hymen, occurring either before or after birth, a condition designated as "imperforate hymen." Congenital, or rather infantile atresia of the hymen leads to a bulging of the hymen as a result of retained secretion in the vagina. Hypersecretion of the uterus at birth is not an unusual phenomenon, and is attributed to the action of some placental agent of the mother upon the uterine mucosa of the infant. Any agent pre-

venting the escape of this secretion leads to vaginal retention. In later infantile life, the uterus remains inactive until puberty, so that in cases of acquired atresia symptoms do not appear until the onset of menstruation.

Usually the painful symptoms of menstruation occur each month with severe lower abdominal cramps and backache, but without vaginal bleeding. Cases have been reported where no symptoms appear until the collection has grown sufficiently large to produce pressure. At first, the

accumulated blood distends the vagina only. As the collection increases, the cervix dilates and the uterus fills with blood, giving rise to an hematometra. Unless relieved, the process may continue and lead to unilateral or bilateral hematosalpinx.

Radical excision of the hymen offers the only sure cure of this condition. The operation must be performed under strict asepsis, and by carefully excising the hymen, free drainage is offered and the incidence of sepsis markedly reduced.

The outstanding symptoms that suffice to clinch the diagnosis are periodic symptoms which usually accompany menstruation, the absence of blood, closure of the vagina, and the presence of a fluctuating, doughy mass in the vagina found in the course of a rectal examination.

A rare symptom is retention of urine caused by pressure on the urethra. The author wishes to report two cases of which urinary retention was the prominent symptom.

Case 1.—A. B., female, aged 12, was first seen March 12, 1929, complaining of recurrent attacks of urinary retention for 36 hours requiring catheterization. The patient had never menstruated.

Physical examination revealed a distended bladder reaching to midway between the symphysis pubis and umbilicus, and a bulging mass between the labia. Rectal examination disclosed a doughy, fluctuating mass filling the vagina and cul-de-sac of Douglas. Examination of the introitus revealed an imperforate hymen. A diagnosis of hematometra was made and operation advised.

Operation, March 13, 1929.—Under ether narcosis the vulva was prepared, an aspirating needle introduced into the vagina, and old blood obtained. The entire hymen was excised and the edges sutured. About 1,000 c.c. of old blood was evacuated and the vagina was irrigated with warm boric acid solution. After five days, the patient was discharged well.

Case 2.—H. K., a girl, aged 12, was first seen May 11, 1931, complaining of low abdominal pain and inability to urinate, of one day's duration. She had never menstruated. Twenty-four hours previously, she had felt a swelling in the lower abdomen and was unable to urinate. One and one-half quarts of urine were drawn by catheter. Six hours prior to the present consultation she again found that she could not urinate.

Physical examination revealed a well developed girl who appeared much older than her age of twelve. Save for a bladder which reached to midway between the symphysis pubis and the umbilicus, the examination was apparently negative. Due to the age of the patient and her reluctance to be examined, rectally, the examination was unfortunately omitted at this time.

The cystoscope encountered an obstruction at

the vesical neck. In order to overcome it, it was necessary to pass straight sounds, following which the cystoscope could be made to enter the bladder; but in doing so, it was necessary to depress the ocular at an angle of 45 degrees. The bladder wall was found thickened and trabeculated, while the ureteral orifices appeared normal. There was a definite elongation of the urethra. The ureter catheters passed easily to both kidneys and disclosed considerable retention. The phenolsulphonophthalein concentration was good on both sides.

Flat roentgenograms and intravenous pyelography failed to show any abnormality.

From these findings, a tentative diagnosis was made of congenital malformation of the urethra. The urethra was dilated with straight sounds which apparently gave her great relief. However, from July 16th to September 1st, she had two attacks of retention requiring catheterization. It was following the last attack that a rectal examination was insisted upon and made, revealing a large, doughy, fluctuating mass in the vagina and cul-de-sac of Douglas. A careful inspection of the introitus disclosed an imperforate hymen, thus clinching the diagnosis of hematometra.

Operation, September 4, 1931.—Under ether narcosis the vulva was thoroughly prepared, as aspirating needle introduced and old blood obtained from the vagina. The entire hymen was excised and the edges sutured with interrupted catgut sutures. About 1,400 c.c. of old blood escaped following incision of hymen, and the vagina was then irrigated with warm iodine solution. After five days the patient was discharged from the hospital well.

Acute retention of urine, though relatively common in men, especially when associated with prostatism, is of considerable interest when found in a female patient because of its rarity. This is particularly true when the cause of the obstruction is an hematometra. The rarity of this condition is attested to by the paucity of cases reported in the literature. In the first case, the diagnosis was easily made at the first examination because of the presentation of all the classical symptoms of this condition. Failure to perform a rectal examination on the second patient was responsible for the delay in making the diagnosis at the time of the first examination.

In both cases the retention of urine was due to a compression of the urethra by the retained blood in the vagina, associated with an angulation of the urethra as a result of the forward pressure of the blood-filled uterus upon the posterior wall of the bladder.

RECORDED AND RESIDENT DEATH RATES IN NEW YORK STATE

By J. V. DE PORTE, Ph.D., ALBANY, N. Y.

Director, Division of Vital Statistics, New York State Department of Health.

V—MATERNAL MORTALITY, 1927-1930

MATERNAL mortality is now generally recognized as a major public health problem. Together with the realization of the great loss of life associated with the basic process of nature came also the disquieting discovery that the risk of death in childbirth, as shown by published figures, is apparently higher in this country than in most of the other civilized countries of the world. Here it is important to consider the fact that rates of mortality from puerperal, as well as other causes, may be compared only when the original data from which they are derived are essentially similar. This, however, is not always the case, mainly because of differences in procedures governing the selection of a primary cause when two or more are given on a death certificate. If the practice of one country is to give preference to a puerperal condition over other causes, while another follows an opposite practice, the maternal mortality of the first country may, because of this reason alone, appear higher than that of the second. As an excellent illustration of this point let us consider the mortality from puerperal septicemia in the two main divisions of the same American State—New York. The vital statistics for New York City are compiled by the City Department of Health; the vital statistics for the rest of the State by the State Department of Health—the two Departments employing different methods of statistical treatment of puerperal deaths. The U. S. Census Bureau re-edits the transcripts of death certificates which it receives from all states of the Registration Area, including, of course, the entire State of New York. In 1929 the New York City Department of Health recorded 117 deaths from puerperal septicemia; the corresponding figure for New York City is given by the Census Bureau as 226. In the same year the State Department of Health recorded 188 deaths from puerperal sepsis Upstate—the Census Bureau, 201 deaths. In other words, the mere change of statistical procedure increases the recorded mortality from puerperal sepsis by 93 per cent for New York City and 7 per cent for the rest of the State. A discussion of mortality from puerperal sepsis in New York City would tell one story if the figures were culled from the City reports and give a less favorable account if the Census figures were employed. If a variation of such magnitude may exist within the confines of a single state, one can readily imagine the degree of possible divergence when conditions in dif-

ferent countries are compared. No rigid conclusions, therefore, should be drawn from international comparisons without a thorough acquaintance with the statistical practice of each country.

Another important fact in connection with maternal mortality is its almost level trend. In the State of New York the average annual death rate in the five-year period 1915-1920 (excluding the epidemic year 1918) was 53.0 per 10,000 births (including stillbirths); in 1921-1925 the rate was 54.4, and 53.8 in 1926-1930. The absence of a downward trend is a condition that is not peculiar to this State. It is generally true for this and many other countries. For example, the annual report of the Registrar General of Scotland for 1930 states that "the mortality from this group of causes (puerperal) has shown no favorable change for many years past." In 1929 the Chief Medical Officer of England and Wales found it "disappointing to be unable to report any definite tendency towards the reduction of the maternal death rate, especially as all investigation indicates that it might and should be substantially reduced." Similarly, in 1929, in New Zealand, whose low general mortality and particularly the very favorable infant mortality place it in an enviable position among the civilized countries of the world, the Director-General of Health found "the reduction of deaths from these causes (puerperal) . . . a perplexing problem."

To sum up: (1) It has not yet been *proven* that the maternal mortality rate of the United States is higher than almost anywhere else in the world; (2) It is a fact that the maternal mortality rate has not shown a downward trend, but this is also true of many other countries.

A comparison of the puerperal death rates in the various subdivisions of the State of New York (outside of New York City) is free of the fallacy pointed out above since the editing of the death certificates for this entire area is done by the State Department of Health. There is, however, another source of possible statistical error, namely, the element of residence. In order to measure the risk of mortality from causes associated with childbirth, the actual number of these deaths must be related to the number of women subject to that risk—in other words, those who were in the puerperal state during the year. This number equals the sum of live and stillbirths, abortions, and miscarriages. Since abortions

and miscarriages are not reported, the denominator of the fraction is of necessity limited to the sum of live and stillbirths; the error due to the omission is, however, comparatively small. A large proportion of births and puerperal deaths occur in hospitals and are recorded in the places in which these hospitals are located. Many of the mothers are non-residents and for this reason the recorded rates often give a distorted picture of local conditions. A correction for residence eliminates this source of error.

Main Divisions of the State, exclusive of New York City. The recorded and resident maternal mortality rates of the State, exclusive of New York City, and of its urban and rural subdivisions in 1927-1930 are shown below:

	Recorded				Resident			
	1927	1928	1929	1930	1927	1928	1929	1930
New York State (exclusive of New York City)	60.5	62.5	58.4	57.1	60.5	62.5	58.4	57.1
Urban	69.3	72.8	68.5	64.5	61.3	64.3	61.7	56.6
Rural	37.6	33.8	31.9	36.7	59.0	59.0	52.1	58.1

The allocation of births and of maternal deaths practically equalizes the rural and urban mortality. In fact, in 1930 the resident rural rate was even higher than the corresponding urban rate by 3 per cent, while the recorded urban rate exceeded the recorded rural rate by 76 per cent.

It may be of interest to quote the actual numbers of recorded and resident births and deaths in one year—for example, 1930. The number of births recorded in the urban part of the State, exclusive of New York City, was 67,983; included in this total, however, were 6,662 births to mothers most of whom were residents of rural New York. On the other hand, the number of births recorded in rural New York was 25,648, considerably less than the resident total—33,531. The recorded urban birth rate was 19.1 per 1,000 population; the resident rate, 17.2. The corresponding rural rates were 12.4 and 16.3.

The number of women who died in the urban territory from causes associated with pregnancy was 455; of these, 100 were rural residents, making 355 as the total of deaths of residents of urban Upstate communities. The relation between the recorded and resident totals in rural New York was quite opposite to that of the urban territory, the number of residents, 199, being more than double the recorded total, 97.

Cities. In each of the four years, 1927-1930, the resident rates of maternal mortality were lower than the recorded figures in practically all cities and large villages, with the exception

of the group of smaller places—from 2,500 to 10,000 population.

Below are shown the rates in 1927-1930 of Buffalo and Rochester, and of the other urban places of the State grouped according to population:

	Recorded				Resident			
	1927	1928	1929	1930	1927	1928	1929	1930
Buffalo	71.4	71.6	73.2	63.2	65.4	64.9	67.3	53.2
Rochester	52.5	77.2	47.7	56.6	42.0	68.3	46.7	53.9
Places								
100,000-250,000	65.4	64.4	59.9	64.9	54.0	49.3	51.1	57.4
Places								
50,000-100,000.	67.0	66.6	69.9	48.6	64.0	59.3	67.4	41.6
Places								
25,000-50,000..	77.4	72.6	62.4	74.3	68.5	62.3	45.1	54.8
Places								
10,000-25,000..	78.7	83.3	84.6	70.5	59.6	65.5	57.5	48.7
Places								
2,500-10,000...	64.3	71.7	67.4	67.5	66.9	71.9	77.1	71.0

Rural Area of Counties. The resident maternal mortality rates of the rural areas of most of the counties were higher than the recorded figures. Each year there were several counties whose resident rates were lower; these, however, were definite exceptions since in no single instance was this favorable relationship between the rates sustained throughout the four-year period.

In considering the rates of maternal mortality computed on the basis of residence we must stress the fact that they represent a correction for the single factor of residence. Neither the recorded nor resident rates give a mathematically accurate measure of local mortality since the recorded rates pre-suppose that *all* deaths are chargeable against the place of their occurrence; the resident rates, that they all would have occurred if the mothers had been delivered in their permanent place of residence, *none* of the deaths being the result of local environment and treatment. Nevertheless, the two sets of rates have definite value, since they enable us to see the situation from two points of view: the recorded rates tell us what is happening in geographical areas; the resident rates, what is happening in groups of population regardless of temporary change of residence.

* * *

This completes the discussion of certain recorded and resident death rates in the State of New York. Tables of these rates for individual cities and counties are published in the annual reports of the State Department of Health. In response to numerous requests these tablets have been reprinted in separate form. Requests for copies, addressed to the Division of Vital Statistics, will be gladly complied with so long as the limited supply lasts.

Annual meeting, Hotel Statler, Buffalo, N. Y., May 23-25, 1932

COMMITTEE ON LEGISLATION

The Journal goes to press at an inopportune time for reporting the activities of the Committee on Legislation. The Legislature is scheduled to adjourn on March 11, and its closing hours are likely to be crowded with business, and unexpected situations arise in regard to the passage of bills. However, the session may properly be

classed as quiet so far as medical legislation was concerned. The compulsory county health department bill does not seem to have been considered, and cult legislation was sidetracked. A summary of medical legislation during the winter session will be published in the Journal of April first.

MEDICAL PROGRESS

The Misinterpretation of Cecal Irritation as Gastric Disturbance.—In many cases of chronic appendicitis of the "masked" form, H. A. Stappert says that the true site of the pain is concealed by absence of tenderness over MacBurney's point, and by the presence of epigastric pain. He found so many patients insisting that their pain was over the stomach, in cases that gave evidence of being chronic appendicitis, that he kept a record for a year to determine the percentage of appendicitis patients who complain solely, or chiefly, of epigastric pain, and also, how many appendix cases refer their pain to the region of the cecum. In a total of 230 cases, 177 patients complained of epigastric pain; in 158 this was the only seat of pain, and in 19 it was the principal seat. Analyzing the 177, he found upon examination that 87 were cases of appendicitis, while 90 were due to other causes. Of the 87 cases, further subdivided, 46 were proved cases and 41 probable cases of appendicitis. Accordingly 26 per cent, or one-fourth, owed their pain to proved appendicitis. If probable appendicitis is included with the proved cases, the proportion becomes one-half instead of one-fourth who complained of epigastric pain alone as the result of appendicitis. Following up the second question, Stappert found that of 60 proved appendicitis cases, only 7 referred their pain to the region of the cecum. If the probable cases are also included, only 8 of 113 patients referred their appendix pain to this region. The reason for this is not hard to understand. It is the rule for acute cases of appendicitis running a stormy course to begin with epigastric pain; not until a few hours later does the pain become localized in the right lower quadrant. According to the view of surgeons and pathologists, this is the moment at which the parietal peritoneum is attacked by inflammation. If for any reason the inflammatory process comes to a halt before this, the pain remains in the epigastric region. There are far fewer cases that follow the severe course outlined in the class-room than there are cases that run a slower course or become stationary at some stage of the inflammatory process. For the diagnosis of appendicitis not one point, but an entire field, comes in question, with processes radiating to the epigastrium. The sensitivity lies chiefly in a line drawn from MacBurney's point to the epigastrium, passing to the right of the umbilicus.—*Münchener medizinische Wochenschrift*, January 8, 1932.

The So-Called Malignant Degeneration of Benign Tumors.—Mariano Cusani raises the question whether a malignant tumor appearing as a degeneration of the elements of a previously benign tumor is really such, or is rather a purely concomitant appearance of a malignant neoplasm that has arisen in a benign tumor in just the same way that it might develop at any other site, as for example on some cicatrix. Thus two different hypotheses may be assumed: (a) That the tumor of malignant nature comes to birth, through some homogeneous stimulus or other upon benign neoplastic tissue, and as such goes through its evolutive cycle independently of any influence from the benign tumor in which it arose, just as it might develop and live through its life's span in any other tissue. (b) That the benign tumor, or rather the elements constituting it, at some moment in their existence, undergo multiple degenerative processes, as may happen in any other type of degeneration, losing their character of benignity and acquiring multiplying and infiltrating characters of aimless, atypical and disorderly proliferation, giving place to a malignant blastoma. Neither of these hypotheses can withstand all criticism. The problem is one that lies at the very bottom of the etiology of tumors. It is a question of cell biochemistry, first and foremost. Not chiefly in its morphology, but in its vital processes does the malignant neoplastic cell reveal a profound and intimate alteration, modifying its attitude with regard to the organism. When we know how and why the malignant tumor originates, we shall also know how and why it can originate upon a benign tumor. When we are able to demonstrate that even in benign tumors the cells have a biochemical behavior different from that of normal cells, one which is in fact more nearly related to that of malignant neoplastic cells, we shall be justified in affirming that the benign tumor cells, even though they may seem benignant so far as their morphology goes, are not actually so, but are possessed of biochemical attributes that enable them under some circumstance or other to explode into their true form from one minute to another. In that case we shall be able to exclude the possibility of a benign tumor degenerating into a malignant one, and to affirm the other possibility as a fact, that the malignant tumor may develop upon the benign one as a simple concomitant event.—*Riforma medica*, December 21, 1931.

Etiology and Pathogenesis of Cardiac Infarcts, of Large Plaques of Sclerosis and of Adhesive Intraventricular Coagulations—There is generally a common pathogenesis, says J Paviot, writing in the *Journal de médecine de Lyon* of January 20, 1932, of infarcts of the interventricular septum or of the wall of the cardiac muscle, and the large sclerotic plaques which often, though not always, result from them—the plaques of myocarditis, interstitial, chronic or subacute—and this pathogenesis is also shared by adhesive coagulations of the ventricle, whether spontaneous or due to parietal endocarditis. All these lesions have a common basis in a condition of the blood that favors the production of thromboses of arteries or arterioles, or within the heart itself. Two types of cases argue for this: those in which the coronaries show a state of absolute integrity with no trace of atheroma, and those in which, although infarcts are present in the lesser or the greater circulation, associated with lesions of the cardiac muscle, no particle of fibrin has been able to mobilize and start from the ventricles. Such infarcts of the lung or kidney are wrongly attributed to embolisms, when the endothelial lining of the endocardium is intact upon the surface of sclerotic plaques on areas of myocarditis of the wall. The histologic study, moreover, of these lesions of infarctoid distribution in lung or kidney reveals only a slow inflammatory focus with arteries or arterioles blocked by blood coagulations which become organized by budding of the arterial wall, the tissue where obliteration has taken place itself tending to be overrun by new formed vessels. Judging from its association with myocardial lesions that are often of long standing, the etiology shows that ganglionic pulmonary tuberculosis, more or less heurled, is frequently the cause of the thrombosis. Besides tuberculosis, there are the other great infections which bear a causative relation, and for intracardiac coagulations can cers, even those not ulcerated, may at times be incriminated. In short, those diseases which are known to be most frequently the origin of intra arterial and intravenous coagulations are found also to give rise to these great myocardial lesions, while syphilis, on the other hand, certainly does have the effect of producing arteritis.

The Problem of Agranulocytosis—According to R Kosiner, the subject of agranulocytosis is of very great interest today, on account of its hitherto extremely unfavorable prognosis. This syndrome must be clearly distinguished from the septic infections from the sympathetic leucopenias and also from aleucemia, by its overwhelming predominance in

the female sex, and by the presence of ulcerated processes in the oral cavity, subicterus, frequently enlargement of liver and spleen, with absence of hemorrhagic diathesis, and with normal red blood picture and platelet count. The idea that agranulocytosis is a special form of sepsis is no longer tenable. There is a tendency, instead, to regard this peculiar blood picture as an essential disease developing on the basis of a constitutional predisposition, and to view it as the result of a myeloid increment or of hormonal influences, on account of its predilection almost exclusively for the female sex. Kosiner reports a case in a woman of 37, which terminated in complete recovery. On admission the leucocyte count was 300, with a normal red blood picture. The characteristic condition was present in the oral cavity, and the patient gave the impression of being gravely ill. She was given a blood transfusion, and two irradiations, first of the femurs and four days later, of the upper arms, in order to stimulate the bone marrow. The response was prompt, the leucocytes rising to 22,000 at the end of a month, then gradually falling until after four months more they were 7,600. This case was atypical in the fact of an initial thrombopenia, the platelet count being on admission only 9,300, and rising under treatment to 320,000. This suggested the presence of an injury affecting two systems. That this was not a case of hormonal thrombopenia dependent on the menstrual cycle was shown by a later normal platelet count in the premenstruum. The case is comparable nosologically to those reported by Zadek and others in which the condition began as agranulocytosis and ended as aleucemia with diminution of platelet count and a hemorrhagic tendency. We do not know the factors which determine whether one blood system or several shall be affected. The successes obtained by use of irradiation bring this question into the foreground—*Deutsche medizinische Wochenschrift*, January 22, 1932.

Treatment of Acute Lobar Pneumonia by Artificial Pneumothorax—During an investigation into lobar pneumonia J J Coghlan discovered that the induction of artificial pneumothorax favorably influenced the course of the disease. He reports in detail his observations in six cases thus treated. From this experience he concludes that the most obvious clinical result is that the induction of artificial pneumothorax initiates a series of events almost indistinguishable from the crisis which normally occurs in this disease. Thus control of the pneumonic process was at first only temporary, persisting merely as long as air remained in the pleural cavity. It was found that the absorptive capacity of the pleura in

this disease is abnormally high. By adequate refills, however, this return of the disease could be forestalled, and when the artificial pneumothorax control had been maintained for a sufficient length of time (about forty-eight hours) the pathological process was definitely brought to an end. The routine procedure suggested for the average case is as follows: (1) Preliminary medication one hour before induction with $\frac{1}{4}$ grain of morphine. (2) Thorough local anesthesia with novocaine down to and including the parietal pleura. (3) Thorough asepsis during induction. (4) A preliminary fill of 400 to 600 c.c. of air, run in very slowly during the negative phase of the pressure swing cycle, and with the needle clipped during the high positive phases. (5) A second fill twelve hours later of 300 to 500 c.c. of air. (6) If the pneumonic process is not completely controlled, a third fill of 100 to 150 c.c. of air may be given in another twelve or eighteen hours. (7) Simultaneous exhibition of a suitable diaphoretic and of Felton's serum in appropriate cases. (8) Owing to the very profuse perspiration induced by this treatment, the comfort of the patient is much enhanced by warm sponging and nursing between blankets. (9) In cases in which it is deemed inadvisable to provoke deferescence by crisis, and a gradual fall by lysis is aimed at, three fills of 100 to 150 c.c. at intervals of six hours might be given and further treatment guided by results. A striking feature of all the cases was the rapidity of onset of the artificial crisis; profuse perspiration set in almost as the pneumothorax needle was withdrawn, and cyanosis and dyspnea were relieved in from fifteen to thirty minutes at the most. A fall in temperature was well established in from two to three hours.—*The Lancet*, January 2, 1932, ccxxii, 5653.

Autovaccinotherapy in Asthmatic Syndromes.—Enrico Frola, writing in the *Riforma medica* of January 9, 1932, says that in bronchial asthma we have to distinguish a local bronchial condition and a general neurotic condition of the entire system. Each of these, the first, presents a constitutional and an acquired factor. The former is represented by a sensitive diathesis at the expense of the local localization, and the latter by a sensitive diathesis, due to the effect of or become situated upon the vegetative nervous inflammatory processes which may be animal, appendicitis, notarial or autogenous toxic processes in question. In the case of bronchial asthma is the epigastrium, upon the elimination or the in a line drawn from the organism toward vago-sympathetic, and upon the correction of the epigastrium. On the basis of these facts, January 12, 1932, look up the problem

of vaccino-therapy. He prepared autogenous vaccines from the sputa of 14 patients suffering with bronchial asthma or asthmatic bronchitis, using the total bacterial flora of the expectoration in each case. He gave first a concentration of 1,000 million germs and later a second one of twice that number. In 4 cases he observed complete cure, in 8 there was marked improvement, and in only 2 were the symptoms unaffected. Nearly all were inveterate cases that had been treated by all the current methods without success. The only contraindications are those met in aged persons with reference to the use of any kind of vaccine, if their blood circulation is poor. The first 2 or 3 injections cause a mild local reaction with a circumscribed erythematous zone, but scarcely any appreciable infiltration. The general reaction had little fever, but was characterized by a slight sense of malaise and headache. This disappeared after the third injection. The method can be recommended for use in any case where the Koch bacillus is not present in the sputum, or where there are no evolutive lesions of the respiratory apparatus.

The Accidents of the Male Climacteric.—Kenneth Walker claims that it is possible to talk of a male climacteric, though it is less noticeable and less well defined than that of women. In the majority of men, during the latter part of the fifth decade and the beginning of the sixth, signs of involution may be noted, upon which the testes exert a controlling influence. The disturbance of endocrine balance is gradual rather than sudden; the male is exempt from the violent flushings of heat, the palpitations and the tachycardia that reveal thyroid dysfunction in the female. There is in the male at this time a disposition to become fat. He may not become generally obese, but accumulates fat both within and on the walls of the abdomen. If the accumulation of fat is excessive, there may be circulatory embarrassment, shortness of breath after exertion and flatulent dyspepsia. Another result of this abdominal adiposity is a liability to develop herniæ. Not infrequently, a patient whose abdominal walls have suffered as a result of over-pressure and under-exercise will complain of pain that is relieved only by lying down. This trouble can be dealt with by the use of a light truss or a well-padded belt. Psychologically a progressively smaller part is played by the active forces in the life of the individual, while inhibitions prevail increasingly. The man who had reached the climacteric becomes less audacious and aggressive, and moves in the direction of conservatism, though there are notable exceptions to this general law. The endocrine readjustments of this period show

themselves, as a rule, in nothing more marked than emotional instability, though not infrequently these disturbances have a sexual character. Most important are the changes in the reproductive system, particularly those of the prostate. This organ increases in size up to the age of 30 and then, progressing less rapidly, reaches its maximum between 50 and 60. After this, in a healthy man, it shrinks steadily to perhaps half its maximum size. The testicle also is likely to suffer. It is during this period that hydroceles are most likely to develop. Microscopical examination invariably reveals patchy fibrosis, associated with changes in the tubules and ducts. The epididymis is likely to be affected by the development of multiple retention cysts. The seminal vesicles likewise show signs of degeneration, and vesicular concretions may form. Their chief importance lies in the fact that they may be mistaken for malignant nodules. The treatment of the male climacteric consists in dealing separately with the various disturbances to which it gives rise. Walker has observed no benefit from attempts to increase the supply of testicular hormone nor from other forms of endocrine therapy.—*British Medical Journal*, January 9, 1932, i, 3705.

The Clinical Management of Movements Occurring as a Leading Symptom Complex in the Neuropathy of Childhood.—The term neuropathy is used here, says Paul Karger, to mean the totality of abnormal responses to stimuli, in so far as they are not caused by demonstrable organic nerve lesions. Movement in the form of voluntary action is dependent on the development of the intellect. A backward child is helped by passive movements of the extremities to make his own efforts, and at length the joy of having overcome difficulty becomes an urge to further development. In addition the urge to imitate becomes a powerful stimulus. This urge may, however, become perverted, and lead to disturbing habits, affected behavior, awkward gait, grimaces, etc. Here we are at the borderline of the pathologic. A habit may become so fixed in a child that he cannot break it voluntarily. Therapy lies in bringing the child's movements again under the control of will. The rational treatment of tic is along this line. The child is asked to make voluntarily the objectionable movement that he cannot overcome. He finds himself unable to imitate it, and fails so signally that the mother recognizes the produced movement as not genuine. The lightning swiftness of a tic movement is impossible to imitate at will; it is associated with a permanent track that acts independently of the will. The longer the child's attention

can be kept upon the exercise of imitating the movements, the better is the prospect of cure. At first the exercises are very fatiguing, and the sign of fatigue, the rest from movement, has the contrary effect, of driving him to take refuge in his tic movements after the exercises. One who watches the child during the exercise is impressed with the concentrated tension of the entire body musculature, even of those parts not engaged in the movement. As tic is only a part symptom of a disturbance in the nervous system, the power gained to repress these movements radiates back to other regions of the system. On this fact rests the good general effect produced in a child by instruction in gymnastics. Children are taught, for example, to carry out a 4-4 rhythm with one hand, and at the same time a 3-4 rhythm with the other, and eventually to carry 3 rhythms at once. The capacity for concentration, which is the purpose of the exercise, has a far-reaching effect on the child's behavior.—*Deutsche medizinische Wochenschrift*, January 15, 1932.

A Case of Peripheral Facial Paralysis in a Healthy Carrier of Diphtheria Bacilli.—In the opinion of Chantriot, facial hemiplegia of diphtheritic origin is less rare than is generally supposed. With Ramond he believes that most paralyzes that are labelled "a frigore" are in reality due to infection, frequently with syphilis, sometimes with grip or other infection. Too little attention has been given to Loeffler's bacillus in this connection. The case reported is that of a boy of 14, with complete paralysis of the right side of his face. When a Wassermann reaction proved negative, a culture was taken from the tonsils, and was found positive for diphtheria. It was learned from the parents that the boy had had an attack of diphtheria two years before, treated with serotherapy, and also that since his recovery no culture had been taken until this time. Chantriot gave a series of 5 injections of anti-diphtheritic serum daily for 5 days, administering 30 c.c. each time. From the time of the second injection the patient began to improve, and the case ended in complete recovery. No other treatment was given. The case shows that while it would be a mistake to suppose that diphtheria toxin is responsible for the majority of paralyzes of the seventh cranial nerve, one should not, nevertheless, always think exclusively of syphilis as the probable cause. It also illustrates the importance of making systematic cultures from the tonsils in every case of paralysis of the seventh pair of cranial nerves, since it is evident that peripheral facial paralysis may be met with in a person who is apparently healthy and yet is a carrier of the Loeffler bacillus.—*Bulletin de l'Académie de Médecine*, December 29, 1931.

LEGAL

RIGHTS AND LIABILITIES IN CONNECTION WITH BODIES OF DECEASED PERSONS

By LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

For many years it has been the settled law that only under unusual circumstances may the dead body of a human being be subjected to an autopsy. The Penal Law in its chapter entitled "Sepulture" imposes very harsh penalties for unlawful dissection of a human body, for removing or stealing dead bodies and the like.

The law authorizes specifically dissection of dead human bodies in four cases: First, when permitted under special statutes, such as the law relative to the manner in which medical schools may obtain cadavers; second, when a coroner's inquest is authorized by law; third, when certain relatives authorize dissection to ascertain the cause of death, and fourth, when a district attorney requires an exhumation in the discharge of his official duties. It is important to note that in the second and third classes of cases the statute expressly restricts the dissection in accordance with the particular inquiry. In other words, if an autopsy is authorized for a certain purpose, those who undertake to perform the autopsy should not perform any dissection beyond the usual autopsy called for under the circumstances.

The courts have long been reluctant to enlarge upon the strict interpretation of the law dealing with dead bodies. Some years ago an application was made under one of the sections of the Code of Civil Procedure to compel a "discovery and inspection" of the body of a deceased person. The action was one to recover damages for the death of the deceased, caused by the alleged negligence of the defendant in an automobile accident. It was the defendant who made the application. The contention was that the law expressly authorized an inspection "of any article or property" within the control of the other party to the action, and it should therefore be interpreted to include the case of the body of a dead person and to permit an autopsy. The court denied the application and reiterated the well established principle that the graves of the dead are regarded as sacred and are by the Penal Laws of the State protected against desecration. The court further ruled that even assuming the law authorized an order for the production and inspection of a buried human body, there clearly would be no authority to permit its dissection. The court in its opinion said:

"These sections of the Penal Law of the State were enacted in the interests of decency, and to

protect the sentiments of sorrowing relatives from outrage. This legislation is an expression and index of our civilization. The 'night encampment' of the dead has for centuries been deemed 'God's acre,' and 'hallowed ground,' and the remains of the dead have been permitted to be disturbed only for urgent and sufficient reasons regulated by statute. * * *

"The defendant asks for permission to 'dissect said body * * * and to examine the contents thereof by microscope, culture and observations,' and it is manifest from the allegations of the petition that nothing less would answer his purposes, or be of any value in arriving at the true cause of Mr. A's death.

"If the article to be inspected were a piece of machinery, instead of a human body, the court, under the section relied on, would not be warranted, we think, in making an order permitting the machinery to be taken apart, and a part of it carried away for the purposes of further examination. Much less could the court be justified in permitting an autopsy on a human body."

The first section of the same chapter of the Penal Law already referred to reads as follows:

"Sec. 2210. *Right to direct disposal of one's own body after death.* A person has the right to direct the manner in which his body shall be disposed of after death; and also to direct the manner in which any part of his body, which becomes separated therefrom during his lifetime, shall be disposed of; and the provisions of this article do not apply to any case where a person has given directions for the disposal of his body or any part thereof inconsistent with those provisions."

By said section it is made clear that a person is entitled in his lifetime to direct the disposition of his body. He may direct an autopsy, cremation and the like, or direct certain other details as to the manner of disposing of his remains. This section likewise has been strictly construed by the courts, for it has been decided that when a deceased person in his lifetime has given the right to another to perform an autopsy upon his body, that right must be asserted promptly if it is to be availed of. This point was decided in a very interesting recent case. In that case a decedent in his lifetime had carried a policy of insurance, one of the conditions of which was that the company should have the right and opportunity to exam-

me the body of the insured and to make an autopsy in case of claim thereunder, unless forbidden by law. The insured died by drowning, and notice and proofs of death were promptly provided the insurance company. Thirteen months thereafter the insurance company contesting the claim applied for an order directing exhumation and examination of the body. The application was denied, the court saying in part:

"The law throws around the bodies of deceased human beings a protection even in their graves. *The right of Christian sepulture includes the right to have one's remains respected in his or her last resting place.* Many circumstances arise from time to time necessitating a disturbance of the repose of the dead, but it must be some controlling public reason or superior private right which would induce the court to permit that to be done which from time immemorial has been considered abstractly as a work of desecration.

"In the absence of a strict legal right, only some rare emergency could move a court of equity to take a body from its grave and permit an autopsy, if there is reason to believe, as exists here that the conscience of the deceased, were he alive, and that the conscience of the surviving relatives, would be outraged thereby, and the sentiments and usages of the religious sect to which the deceased and his relatives belong should not be wholly disregarded.

"The dead are to rest where they have been laid unless reason of substance is brought forward for disturbing their repose.

"* * * The defendant was not at liberty to wait indefinitely or for any unreasonable length of time before making a demand for an autopsy upon the body of the deceased insured. The provision in the policy granting this right called for prompt action on the part of the insurer. It was an unreasonable delay on the part of the insurer to wait for over a year after the body of the insured had been interred, and no sufficient excuse appears for this delay.

"* * * The courts have repeatedly held that in cases of accidental death the insurer must make a demand within a reasonable time for an autopsy. The defendant was not at liberty to wait indefi-

nately or for any unreasonable length of time, although no time is specified within which the permission to examine may be availed of. Still, a due regard for the sentiments of the family and friends of the deceased, even public policy required as early and immediate exercise of the option to examine as was possible. Conditions in insurance policies as in all other contracts, should be construed strictly against those for whose benefit they were reserved.

"Section 2213 of the Penal Law of the State of New York provides for only four instances where the dissection of a human body is lawful. The case at bar does not fall within any of these four provisions. Neither can there be any power vested in the court to order an examination and dissection of this body under the provisions of section 324 of the Civil Practice Act, which gives our courts power to require discovery.

"Section 2210 of the Penal Law, however, seems to recognize the right of a person to direct the disposal of one's own body after death.

"So it is seriously questioned under the authorities above cited whether the court has power to grant the relief sought in this motion and if it has the power under the terms of the policy, it certainly should not be granted at this late day where it is extremely doubtful if an autopsy would reveal anything other than putrefaction."

It will be seen that the court in ruling as it did was acting upon the principles enunciated nearly forty years ago in a somewhat similar case as follows:

"When a body has once been buried, the law, having a proper respect for the dead a just regard for the sensibilities of the living and for the due preservation of the public health has jealously guarded the grave against ruthless intrusion. Exhumation has been tolerated only upon consent of the next of kin, for substantial reasons satisfactory to the family and which appealed to the finest instincts of their nature, or upon permission of the proper municipal authority, in extreme cases, to answer the imperative requirements of justice or some urgent public necessity which overruled the apparent impropriety and made the act legal."

COUNTERCLAIM, CLAIMING FAILURE TO DIAGNOSE ILLNESS

The doctor in this case, who specialized in general medicine was called to the home of a patient, an elderly man, who was found to be complaining of difficulty in breathing.

The doctor examined him and tentatively diagnosed the condition to be asthma and sinus

trouble. Codeine and other medicines were prescribed, and as the man's condition did not improve satisfactorily, in about ten days the doctor advised the patient to enter a hospital for observation and treatment. There numerous examinations were made of his condition, including blood

tests, urine tests and x-rays, and an asthma specialist and a nose and throat man were called into consultation. The diagnosis indicated a severe case of bronchial asthma, sinusitis of the left antrum and left ethmoid and intestinal toxæmia. After four weeks during which time these conditions had improved fairly well, the patient left the hospital and went to his country home where the doctor no longer saw him.

The doctor brought suit for his bill for professional services in the Supreme Court of the State of New York, and the patient appeared, by his attorneys, denying the value of the services and interposing a counterclaim to the effect that the doctor had failed to properly diagnose the illness

and thereby caused him damages for which affirmative judgment was demanded against the doctor. The doctor's counsel sought to obtain a bill of particulars as to the counterclaim, but none was ever provided by the patient's attorneys. An order was then obtained precluding the defendant from giving any evidence at the time of trial in respect to the particulars relating to the counterclaim.

When the case was reached for trial on the calendar no one appeared for the defendant, and on motion of the attorney for the doctor the counterclaim was dismissed. A judgment was obtained for the doctor's bill including interest and the costs of the action.

CLAIMED NEGLIGENCE WITH RESPECT TO BREAKING OF NEEDLE

An employee of a linseed oil factory while engaged at his work accidentally slipped and fell upon a piece of galvanized iron, gashing his wrist. He was taken immediately to a doctor for emergency treatment. The doctor examined the injury and found an incised wound of the inner and anterior surface of the right wrist and that one of the tendons was severed. There was profuse bleeding.

The doctor in his treatment of the wound decided that three or four sutures were necessary, and as he was drawing the needle through the skin for the last of said sutures the needle broke and about three-quarters of the needle remained embedded in the wrist. The doctor made an immediate attempt to remove the broken piece by probing, but as the patient seemed to become very faint from said probing, the doctor decided that to continue his search for the missing piece of needle would be more harmful than helpful, so he dressed the wound and left it partly opened. The wound healed without any evidence of infection in about two weeks, but the patient continued to return to the doctor for treatment complaining constantly of pain. The man apparently was a malingerer and was using the slight injury as a pretext to obtain a large amount of workmen's compensation.

Some weeks later an x-ray was taken and the needle was removed from the man's wrist.

When the man was examined for the purpose of determining the amount of workmen's

compensation he was entitled to, it was observed that the motion in his wrist was slightly restricted due to the injury itself rather than the presence of the needle in the wrist.

A suit was started some time later against the doctor in which it was claimed that due to his carelessness and incompetence in treating the patient, his suturing needle broke off and remained for a long period of time within the plaintiff's wrist and that due solely to the improper treatment on the part of the doctor the plaintiff was unable to use his said hand and wrist for a long period of time.

An answer was interposed on behalf of the doctor in which a special defense was set up that the plaintiff had received full compensation for all of his injuries under the Workmen's Compensation Act. The case remained dormant for a considerable period of time and a motion was made on behalf of the doctor to dismiss the complaint for lack of prosecution. The attorney for the plaintiff appeared in court to oppose the motion on the ground that his client had disappeared and requested the court that he be given an opportunity to locate his client and proceed with the trial of the case. The court directed the adjournment of the motion for one week to give the plaintiff's attorney the opportunity he desired. On the adjourned date no one appeared in behalf of the plaintiff and the court dismissed the case, finally terminating the matter in favor of the doctor without trial.

NEWS NOTES

PHYSICAL THERAPY COURSES

The Committee on Public Health and Medical Education, in cooperation with the Physical Therapy Committees in New York and Bronx Counties, arranged for a course on physical therapy in traumatic conditions for these two counties. Beginning February 9th, the following set of lectures was given at the New York Academy of Medicine, on successive Tuesday and Thursday afternoons:

February 9th: "Indications and Contraindications," Wm. V. Healey, M.D.

February 11th: "Uses and Technic of Superficial Heat Measures," Heinrich F. Wolf, M.D.

February 16th: "Uses and Technic of Diathermy," Wm. Bierman, M.D.

February 18th: "Uses and Technic of Massage and Therapeutic Exercise," Kristian G. Hansson, M.D.

February 23rd: "Electrodiagnosis, Galvanic and Low Frequency Currents," Richard Kovacs, M.D.

February 25th: "The Compensation Viewpoint," Herman L. Reis, M.D.

Following the lecture course, practical demonstrations of the work were held at the physical therapy departments of the following institutions: Beth Israel Hospital, Hospital for Joint Diseases, Hospital for the Ruptured and Crippled, Montefiore Hospital, Mount Sinai Hospital, Polyclinic Medical School and Hospital, Reconstruction Unit of Post-Graduate Hospital, Vanderbilt Clinic.

There was great interest shown, and the average attendance at the lectures was seventy. Participants were assigned to the clinics in groups of ten for two periods during two successive weeks of the course.

COMMITTEE ON LEGISLATION

BULLETIN No. 5

February 23, 1932.

Since the issuance of our last bulletin the following bills have been introduced:

Senate Int. No. 1083—Mr. Webb has introduced the osteopathic bill which Mr. Garnjost has been carrying in the Assembly.

Senate Int. No. 1140—Thayer; would require the state to pay \$100.00 toward expense of birth and caring for health and welfare of a child born in lawful wedlock, claim to be filed with the State Health Department. Referred to the Judiciary Committee. Mr. Thayer states in the bill that one of its objects is to remove in part, at least, the economic question as a cause of birth control.

Senate Int. No. 1169 (concurrent Assembly Int. No. 1305—Coughlin)—Mr. Evans introduces a new section to the Public Welfare Law, providing for the creation of a central registration bureau of hospital clinics in each public welfare district to promulgate rules for application by persons for treatment in hospital clinics. The bill was referred to the Health Committee.

Senate Int. No. 1217—Wicks; to amend the Public Health Law by providing state aid for installation and maintenance of local clinics for treatment of venereal diseases. A mimeographed

copy of this bill is enclosed. Please read it over and at once give us your opinion of its merit. *Remember* the legislature will adjourn on Friday, March 11th, and action will be rapid from now on.

Senate Int. No. 1218—Wicks; to amend the Public Health Law by providing public health nurses must have the qualifications prescribed by regulations of the Public Health Council. Referred to the Health Committee.

Senate Int. No. 1219—Wicks; to amend the Public Health Law relative to the approval of laboratory examinations by the health commissioner, including examiners of pathological specimens.

Assembly Int. No. 1271—Mr. Wallace adds a new section to the Penal Law, making it a felony to willfully or unjustifiably interfere with, injure, destroy or tamper with any horse, mule, dog or other domestic animal used for racing, breeding or competitive exhibition of skill. Referred to the Codes Committee. We are carefully watching this bill to make certain that it will not be confused with the anti-vivisection bill.

Assembly Int. No. 1477—Mr. Robinson adds a new section to the Lien Law giving hospitals lien

tests, urine tests and x-rays, and an asthma specialist and a nose and throat man were called into consultation. The diagnosis indicated a severe case of bronchial asthma, sinusitis of the left antrum and left ethmoid and intestinal toxæmia. After four weeks during which time these conditions had improved fairly well, the patient left the hospital and went to his country home where the doctor no longer saw him.

The doctor brought suit for his bill for professional services in the Supreme Court of the State of New York, and the patient appeared, by his attorneys, denying the value of the services and interposing a counterclaim to the effect that the doctor had failed to properly diagnose the illness

and thereby caused him damages for which affirmative judgment was demanded against the doctor. The doctor's counsel sought to obtain a bill of particulars as to the counterclaim, but none was ever provided by the patient's attorneys. An order was then obtained precluding the defendant from giving any evidence at the time of trial in respect to the particulars relating to the counterclaim.

When the case was reached for trial on the calendar no one appeared for the defendant, and on motion of the attorney for the doctor the counterclaim was dismissed. A judgment was obtained for the doctor's bill including interest and the costs of the action.

COMMITTEE ON LEGISLATION

BULLETIN No. 5

February 23, 1932.

Since the issuance of our last bulletin the following bills have been introduced:

Senate Int. No. 1083—Mr. Webb has introduced the osteopathic bill which Mr. Garnjost has been carrying in the Assembly.

Senate Int. No. 1140—Thayer; would require the state to pay \$100.00 toward expense of birth and caring for health and welfare of a child born in lawful wedlock, claim to be filed with the State Health Department. Referred to the Judiciary Committee. Mr. Thayer states in the bill that one of its objects is to remove in part, at least, the economic question as a cause of birth control.

Senate Int. No. 1169 (concurrent Assembly Int. No. 1305—Coughlin)—Mr. Evans introduces a new section to the Public Welfare Law, providing for the creation of a central registration bureau of hospital clinics in each public welfare district to promulgate rules for application by persons for treatment in hospital clinics. The bill was referred to the Health Committee.

Senate Int. No. 1217—Wicks; to amend the Public Health Law by providing state aid for installation and maintenance of local clinics for treatment of venereal diseases. A mimeographed

copy of this bill is enclosed. Please read it over and at once give us your opinion of its merit. Remember the legislature will adjourn on Friday, March 11th, and action will be rapid from now on.

Senate Int. No. 1218—Wicks; to amend the Public Health Law by providing public health nurses must have the qualifications prescribed by regulations of the Public Health Council. Referred to the Health Committee.

Senate Int. No. 1219—Wicks; to amend the Public Health Law relative to the approval of laboratory examinations by the health commissioner, including examiners of pathological specimens.

Assembly Int. No. 1271—Mr. Wallace adds a new section to the Penal Law, making it a felony to wilfully or unjustifiably interfere with, injure, destroy or tamper with any horse, mule, dog or other domestic animal used for racing, breeding or competitive exhibition of skill. Referred to the Codes Committee. We are carefully watching this bill to make certain that it will not be confused with the anti-vivisection bill.

Assembly Int. No. 1477—Mr. Robinson adds a new section to the Lien Law giving hospitals lien

on any rights of action, suits, claims, etc., of any person admitted to hospital on account of personal injuries as result of negligence of any other person or corporation. Referred to the Judiciary Committee. We have talked with Mr. Robinson about having the doctors included and he said that we could not do that without adding, also, the nurses, and he stated that he hoped by limiting the lien to the hospitals, he could avoid much of the opposition that was brought against the bill the last couple of years. He suggested that if this bill could be passed, he would be only too glad to sponsor an amendment next year, adding the doctors and nurses, and he felt that there was a strong possibility of being able to accomplish our desires if we took it piecemeal. His expression was: "A half-loaf is better than none." The bill is much better drawn than in previous years and a printed copy will be sent out as soon as available.

Mr. Dickey introduced in the Assembly a resolution asking for the creation of a committee to investigate the narcotic drug problem in the state. The committee is to be a joint legislative committee consisting of two members of the Senate and three of the Assembly. It carries a budget of \$25,000.00. It was introduced last evening and tabled, but will be brought out for final action later in the week.

ACTION ON BILLS

The Westall-Gamble bill (Senate Int. No. 256, Assembly Int. No. 473), providing that the county board of health shall have three instead of two physicians, has passed both houses and will now go to the Governor.

Senate Int. No. 159—Pitcher; Assembly Int. No. 440—Jenks; relative to the commitment of certain mentally defective persons to state institutions, has passed the Senate and reached third reading in the Assembly.

Senate Int. No. 415—Pitcher; Assembly Int. No. 591—Austin; relative to licensing of private institutions for care of persons with mental disorder, has passed the Senate.

Senate Int. No. 444—Hanley; Assembly Int. No. 526—Ostertag; permitting hospitals to have

a one hundred dollar rotating fund, has reached third reading in the Assembly.

Senate Int. No. 635—Wicks; Assembly Int. No. 793—Austin; relative to requirements to practice midwifery has reached third reading in both houses.

Senate Int. No. 636—Wicks; Assembly Int. No. 792—Austin; regarding the recording of births, has reached third reading in both houses.

We have been unofficially informed that the Vaughan anti-vivisection bill was killed in committee. We are not certain what effect this action will have on the Bernhardt bill, which is identically the same, but presume that it indicates that the latter bill will receive the same fate. Today, however, a companion to these two bills was introduced in the Senate by Mr. Wicks. The Wallace bill, Assembly Int. No. 1271, was introduced in the Senate by Mr. Thompson, Int. No. 1236.

This afternoon, at the request of the Committee on Public Education in the Assembly, Dr. Lawrence appeared before them for the purpose of answering questions they might have regarding the osteopathic bill. At the same time Dr. Downing appeared in behalf of the osteopaths. The committee asked a great many questions and seemed to be thoroughly impressed with the seriousness of giving osteopaths permission to use such a large group of drugs as they have requested the privilege of doing.

Both houses have finally voted to adjourn on March 11th and all committees in the Assembly will be discharged on Wednesday, March 2nd.

HEARINGS

Mr. Austin has announced a hearing for Tuesday, March 1st, at 9:45 A.M., on Assembly bill Int. No. 1097, which relates to the powers of the Public Health Council, and Assembly Int. No. 1190, which relates to the pollution of waters by industrial waste.

HARRY ARANOW,
JOHN J. BUETTNER,
MARSHALL CLINTON,
Committee on Legislation.

LETTER TO COUNTY SOCIETY LEGISLATIVE CHAIRMEN

February 23, 1932.

Dear Doctor:

Enclosed you will find the following bills:

Senate Int. No. 967—Thompson; to amend the Mental Hygiene Law in relation to the care and treatment of veterans of all wars at Kings Park Hospital. The object of this bill is to make available to the veterans of the Spanish-American

War facilities in the hospital built by the state for the veterans of the World War. This bill was not prepared by the Department of Hospitals and we are not sure that it has the support of the American Legion.

Senate Int. No. 994—Wicks; to amend the Public Health Law in relation to board of visitors. The object of this bill is to reconstruct the board

of visitors of the State Institute for the Study of Malignant Disease at Buffalo.

Senate Int. No. 995—Wicks; to amend the Public Health Law in relation to the pollution of waters. This bill is practically the same bill which has been before the legislature for several years. The object is to give the Commissioner of Health control over pollutions other than sewage, because some drinking waters are now being polluted by industrial waste.

Assembly Int. No. 1097—Austin; to amend the Public Health Law in relation to powers of Public Health Council. Let us urge that each one of you read this bill very, very carefully, and give us immediately your reaction. It doesn't require a great deal of explanation; you can see very readily what extensive powers this would give the Public Health Council and it is for you to decide and let us know whether you think this is a good

bill. Of course, this does not apply to Greater New York and it is being sent to the chairmen of those five county Societies largely as a matter of information.

Assembly Int. No. 1165—Mr. Cuvillier has re-introduced his cancer clinic bill of last year. In our opinion, it is very unwise that this proposed legislation should be enacted, and we feel that Mr. Cuvillier will find it necessary to do an enormous amount of educational work before he can expect the state to appropriate one million dollars for welfare work of this character.

Assembly Int. No. 1167—Mr. Cuvillier's omnibus bill of former years. It is identically the same bill as he has presented in previous years.

HARRY ARANOW,
JOHN J. BUETTNER,
MARSHALL CLINTON,
Committee on Legislation.

LETTER TO COUNTY SOCIETY LEGISLATIVE CHAIRMEN

February 26, 1932.

Dear Doctor:

Enclosed you will find the following bills:

Senate Int. No. 1140—Thayer, states that it is an effort to counteract birth control by granting a mother \$100.00 to be used to defer the expenses of the birth of a child. If from this amount the physician were sure to be paid, it might be well worth our supporting the bill.

Senate Int. No. 1169—Evans; to amend the Public Welfare Law in relation to a central bureau of hospital clinics. Let us urge that you study this bill carefully. It originated in New York City, where social welfare organizations have been developing a scheme along this line voluntarily. The Albany Council of Social Agencies, in conjunction with the Albany County Medical Society, has also been discussing a similar scheme. At a meeting of the legislative chairmen of the county Societies in the western section of the state, held in Buffalo on Thursday night, the president of the Erie County Society expressed himself as heartily in favor of the bill and thought that it is most essential that a

scheme of this kind be immediately inaugurated for Buffalo.

Senate Int. No. 1218—Wicks; to amend the Public Health Law so as to make it clear that nurses appointed to do public health work shall qualify in accordance with the regulations of the Public Health Council.

Senate Int. No. 1219—Wicks, to amend the Public Health Law so as to give the Public Health Council authority to approve pathologists employed in public health laboratories.

Assembly Int. No. 1477—Robinson. This is the lien bill that we have all been looking for. Read it over very carefully and give us immediately your reaction.

Remember that the legislature has voted to adjourn March 11th and Assembly committees will be discharged from further consideration of all bills on Wednesday, March 2nd.

HARRY ARANOW,
JOHN J. BUETTNER,
MARSHALL CLINTON,
Committee on Legislation.

SPECIAL BULLETIN

March 1, 1932.

As announced, the Assembly Public Health Committee held a hearing this morning on the Austin bill, Assembly Int. No. 1097, and there appeared in opposition to the bill the president,

treasurer and three other members of the Sanitary Officers' Association; the Commissioners of Health of Buffalo and Troy; Dr. Hambrook, representing Rensselaer County; and Dr. Lawrence for the Committee on Legislation.

Dr. Lawrence's principal objection was that the bill as drawn would give the Public Health Council too extensive powers. He also objected to the vagueness of the bill; for example, the phrase on page 2, line 12, "and other health officers"; and again in lines 14 and 15, "and other professional or technical positions in state and local public health service."

Commissioner Parran appeared in support of the bill. The committee was obliged to recess before the hearing was completed. During the recess, Commissioner Parran discussed the bill with its opponents and they finally proposed the following amendment:

Beginning on line 9, after the word "officers," strike out everything to the end of line 18 and substitute the following: "county, city and deputy health commissioners and other local health officers hereafter appointed, public health nurses, directors in charge of approved laboratories, medical superintendents of public tuberculosis sanatoria, operators of water purification plants and of sewage treatment works, and county dairy and milk inspectors. The Public Health Council is authorized to establish grades for such positions."

Let us have your reaction immediately to this amendment.

Word has been received that the Regents, at their meeting on Saturday, decided to approve the osteopathic bill. We confess we are amazed that they thought wise to take this action. We wish we might understand how the Regents can so readily reverse themselves, for in 1908, when the medical practice act was adopted recognizing osteopaths as well as physicians, it was explicitly stated that the practice of osteopathy had nothing to do with drugs. The Department of Education states that at least 150 of the osteopaths practicing today were among the group granted those privileges at that time. In the meanwhile these men have made no study of pharmacology and materia medica, all of which is known by the Regents and yet they are willing to say to the public that these 150 men can safely prescribe and administer anesthetics, narcotics, serums and vaccines.

HARRY ARANOW,
JOHN J. BUETTNER,
MARSHALL CLINTON,
Committee on Legislation.

SPECIAL BULLETIN—IMPORTANT !

March 2, 1932.

The Assembly committees yesterday took action upon all bills resting with them before they were discharged. The following action is reported on bills in which we have had an interest:

KILLED

Assembly Int. No. 975—Garnjost—Osteopathy bill.

Assembly Int. No. 949—Killgrew—Physiotherapy bill.

Assembly Int. No. 625—Moffat—Occupational diseases.

Assembly Int. No. 439—Hartshorn—Peddling eyeglasses.

Assembly Int. No. 261—Vaughan—Anti-vivisection bill.

Assembly Int. No. 598—Gimbrone—Habit-forming drugs.

Assembly Int. No. 684—Esquirol—Occupational diseases.

Assembly Int. No. 464—Coughlin—Occupational diseases.

Assembly Int. No. 511—Cuvillier—Automobilists injuring dogs.

Assembly Int. No. 584—Theodore—Free choice of physician or surgeon.

Assembly Int. No. 946—Heck—Tear gas.

Assembly Int. No. 1089—Austin—Board of visitors at Cancer Institute in Buffalo.

Assembly Int. No. 1097—Austin—Powers of Public Health Council.

Assembly Int. No. 1190—Austin—Contamination of water by industrial sewage.

Assembly Int. No. 1165—Cuvillier—Establishment of cancer clinics.

Assembly Int. No. 1166—Cuvillier—Health insurance.

Assembly Int. No. 1167—Cuvillier—(Same as Int. No. 1166).

Assembly Int. No. 1587—Austin—Venereal disease clinics.

Assembly Int. No. 1495—Austin—Qualifications of public health nurses.

REFERRED TO RULES COMMITTEE

Assembly Int. No. 591—Austin—Licensing of mental hygiene hospitals.

Assembly Int. No. 604—Otto—Compensation of health officers.

Assembly Int. No. 1496—Austin—Approval of pathologists for public health laboratories.

Note that the osteopathy and physiotherapy bills were killed in the Assembly. In the Senate, however, the osteopathy bill was reported out by Senator Webb after being instructed that the bill was approved by the Regents.

This morning on third reading the bill was amended by striking out the privilege to use

serums, vaccines and antitoxins. This bill, in spite of this amendment, is still vicious so far as the public is concerned, in that it would permit men with no training to administer and prescribe the powerful narcotics, anesthetics and antiseptics. The bill as amended must be printed before considered, which means that it will not come on to the calendar before Friday or Monday. In the meantime if each chairman will get in touch with his Senator and make it a point to show him how dangerous it would be for these inexperienced and untrained men to handle

opium, morphine and codeine, also to administer intravenously arsphenamine, tryparsamide, neo arsphenamine, and acriflavine, we feel that we can kill the bill in the Senate, which would be the final blow.

May we ask that you request influential patients to write similar letters to the Senators. *It is essential that this action be taken promptly.*

HARRY ARANOW

JOHN J. BUETTNER,

MARSHALL CLINTON

Committee on Legislation

DUTCHESS-PUTNAM COUNTY

A regular meeting of the Dutchess-Putnam Medical Society was held Wednesday, February 10, 1932, at the Nelson House, Poughkeepsie, N. Y. The meeting was called to order by the President, Dr. W. A. Krieger at 8:30 P. M.

Dr. Adolph G. G. DeSanctis, Pediatrician at the Post Graduate Hospital, New York City gave a paper on "Surgical Abdominal Conditions in Children" with lantern slide demonstration.

The discussion was opened by Dr. Card, followed by Drs. Sadler, Harrington, Thomson, Cotter and Breed.

Dr. Asher Lael Baker, of Beacon, was elected to membership.

The following transfers were received:

Dr. Ralph P. Folsom from New York County,

Dr. Henry C. Storrs from Rockland County,

Dr. Ernest S. Steblen from Broome County.

The President made the following committee appointments:

Public Health and Public Relations, Dr. J. A. Card, Chairman.

Legislative Committee, Dr. J. A. Card, Chairman.

Library Committee, Dr. A. L. Peckham, Chairman, Drs. G. E. Lane, J. N. Baldwin, C. T. Cadwell, and G. J. Jennings.

It was regularly voted that a committee be appointed to be called "The Committee of the Dutchess-Putnam Medical Society for the Control of Cancer." The President then appointed the following members: Dr. Helen Palliser, Chairman, Drs. J. E. Sadler and Josiah Coborn.

The Secretary was empowered to purchase twenty automobile emblems.

There were eulogies on the life of Dr. E. M. Burns by Drs. Borst, Sadler and Poucher, who were then appointed a committee to prepare a suitable memorial.

Dr. Card moved that the meeting adjourn out of respect to the late Dr. Burns.

Present: Drs. DeSanctis, Krieger, Borst, Marks, Sobel, Card, Peckham, Cadwell, Poucher, Sadler, Neighbors, Rogers, O'Brien, Dingman, Breed, Cotter, Conger, Gosse, Roberts, Herridon, Benson, Thomson, Harrington, Carpenter, Appel, Rivenburgh, Toomey, Richard, Boyce, Mahoney, Stoller, Simon, and Mr. Whitbeck (32).

H. P. CARPENTIER, Secretary

KINGS COUNTY

The regular stated meeting of the Medical Society of the County of Kings was held on Tuesday, February 16, 1932, in the MacNaughton Auditorium of the Society Building, 1313 Bedford Avenue, Brooklyn.

The following scientific program was presented:

1. Address "Nature of Viruses"

By Thomas M. Rivers, M.D., New York, N. Y., Member of the Rockefeller Institute.

2. Address "Gynecological Conditions and

-Their Treatment in Children and Adolescents"

By Robert T. Frank, M.D., Gynecologist, Mt. Sinai Hospital, New York City.

The activity of the Membership Committee under the chairmanship of Dr. Joseph Rosenthal is seen in the fact that, at the February meeting, seventeen new members were added to our list and thirty-two proposals for membership were presented.

The membership committee has been busy dur-

DOCTOR BILLS

The doctor's side of medical economics is well set forth in the following editorial from the *New York Times* of February 23rd:

"The doctor has only one commodity to sell—his time, valuable because of his brains, training and experience. Unlike the manufacturer, he cannot go into mass production of his goods. Training in college, medical school and hospital, and the slow process of building up a practice fill the years until he is 38 or 40. In the next fifteen or twenty years—for the average life of a doctor is 60 years—he must provide for old age and his family if he is ever to do it. He has endless duties besides seeing patients. He must sit on various committees, be active in medical social service, go to distant cities to make addresses, attend medical meetings and keep up with modern medical literature, be present at luncheon or dinner conferences. He is often teaching fifteen or twenty hours a week. He must make

his living in the few hours a day that are free from outside activities.

"The very fact that the public expects full knowledge and successful treatment from any doctor who is called in is a high compliment to the profession. The patient who complains that three or four doctors were needed before one was found to make a correct diagnosis ignores the time element. Perhaps the first doctor at the later date would have been quite as accurate in interpreting symptoms. The scope of medicine and surgery has so greatly increased in recent years that a diagnosis is no longer a matter of looking at a tongue and taking a pulse. Much unwarranted criticism of physicians may be laid to the fact that each man's health is to himself 'so emotional and personal an affair' that he can scarcely judge his doctor with disinterested intelligence. A throbbing earache will warp the soundest judgment."

BRICKS THAT FLOAT

The *New York Herald Tribune* of January 17, has an editorial discussing a new kind of building brick as follows:

"When walls were three or four feet thick no heat problem arose. Conductivity of winter heat from within outward or of summer heat from outside inward was slow anyway through the thick adobe walls with which building began. As the mechanical side of building has improved and walls have grown thinner, undesired losses or gains of heat have grown more serious. It happens that the best heat insulator ordinarily available is air. That is why a wall of reasonably porous brick or wood is a better heat insulator

than one of solid stone. It is the air in the pores that does the insulating. New materials of the type displayed by Dr. Burgess differ from older ones in two ways. They have more air in their pores, which is why these bricks float in water, and these pores are not connected with one another so that air can seep entirely through them. Air entrapped in the pores inside these floating bricks is held immovably. Heat traverses such materials only very slowly, so that new houses in which such bricks are used not only will be lighter than present ones but will mark another step toward the threefold insulation against heat, light and intrusion which is a house's job."

THE CHIROPRACTIC CONVENTION

The Fifth Annual convention of the American Bureau of Chiropractic was held in the Hotel Pennsylvania, New York City, closing on January 24. The *New York Herald Tribune* of January 25, quoted one speaker as saying:

"For chiropractic to even start to live we must get the news of our work in the papers. There is no way of getting to the people except through the newspapers and the radio. Today syndicated articles on medicine are printed from coast to coast. If chiropractic could put men to work

writing for every newspaper in the country, then you wouldn't have to worry where your next patient was coming from."

A prominent chiropractor said: "The chiropractors cannot influence the Legislature to amend the medical practices act until they become more numerous. We are outnumbered thirty to one by the medical doctors. You can't go to your legislator with that weak strength and hope to have him listen to you. His job depends on votes."

BOOK REVIEWS

THE CARDIAC CYCLE By HARRINGTON SAINSBURY
OBE MD Octavo of 79 pages, illustrated New
York, William Wood and Company, 1931 Cloth, \$1 75

This small volume has been written to present some theories, which the author holds, on the effect of the cardiac cycle on the circulation. The views expressed are unorthodox and no experimental evidence is brought forward to support them. Despite the fact that the changes which are found can be better explained by other means, some points which are raised are of interest.

J HAMILTON CRAWFORD

DEMONSTRATIONS OF PHYSICAL SIGNS IN CLINICAL SURGERY By HAMILTON BAILEY, FRCS Third edition Octavo of 277 pages, illustrated New York, William Wood and Company, 1931 Cloth, \$6 50

The ability successfully to use our five senses in clinical diagnosis has been somewhat dulled by the reliance placed on data supplied by the chemical and X-Ray laboratories.

The textbook now being reviewed is excellently suited to save us from this decadence.

A wealth of physical signs and their consideration as well as methods of physical examination suitable to surgical conditions have been described and systematized in this volume. The illustrations are numerous and are well executed. This volume should be well thumbed by both surgeon and internist.

Geo Webb

COLLECTED PAPERS OF THE MAYO CLINIC AND THE MAYO FOUNDATION Edited by Mrs H M MELLISH-WILSON, RICHARD M HEWITT, BA, MA, and MILDRED A FELKER, BS Volume XXII, 1930 Octavo of 1125 pages, illustrated Philadelphia and London, W B Saunders Company, 1931 Cloth, \$13 00

As mentioned in the foreword of this volume there were 482 papers issued from the Clinic in 1930. Of these 85 are reprinted in full in this volume, 30 are abridged, 55 are abstracted and 312 are mentioned by title only.

Among the articles reprinted in full there are many of general interest dealing with surgery of the biliary tract, the colon including the neuro-surgical approach to Hirschsprung's disease, the G U system and gynecology.

Being representative of an accepted institution of learning this volume is too well known to need any special recommendation.

Geo Webb

THE CAUSATION OF CHRONIC GASTRO DUODENAL ULCERS A New Theory By J JACQUES SPIRA MRCS L.R.C.P. Octavo of 78 pages New York, Oxford University Press, 1931 Cloth, \$2 50 (Oxford Medical Publications)

This small pamphlet of 75 pages is devoted to a presentation of a theory of the causation of gastric and duodenal ulcer.

The argument is best stated in an introduction by Humphrey Rolleston "fat when introduced into the stomach regularly causes regurgitation of the duodenal contents including bile into the stomach, and bile salts, when mixed with the acid gastric contents damage the mucous membrane of the stomach. Evidence in favor of the accuracy of these various events is provided by reference to the work of others and attention

is drawn to the analogous acute damage effected in the pancreas when bile passes into its ducts. Fat inhibits gastric movements, delays digestion and though valuable from its continued vitamins is necessary in small quantities only."

In short, chronic peptic ulcer of the stomach and duodenum is caused by eating too much fat. How the author would account for the enormous increase in the number of cases of gastro duodenal ulceration in the fat-starved Europe of the war we do not ask.

J E J

A TEXTBOOK OF MEDICAL DISEASES FOR NURSES INCLUDING NURSING CARE By ARTHUR A STEVENS, A.M., M.D., and FLORENCE ANNA AMBLER, B.S., R.N. Octavo of 503 pages illustrated Philadelphia and London, W B Saunders Company, 1931 Cloth, \$2 75

In their preface to this volume the authors state "The scope of the book is complete in that it deals with the various diseases—their etiology, pathology, symptoms, diagnosis, complications, prognosis and treatment—and, in addition, their nursing care." A perusal of the book soon reveals that the authors have not overstated the case for nearly all the clinical entities that man is heir to, from measles to kala azar, are discussed in more or less detail. Following the chapters devoted to the commoner maladies the authors present an outline of the essentials of the nursing care of patients who may be suffering from the disease under discussion.

An appendix contains a description of such procedures as hypodermoclysis, Murphy drip, alcohol sponge, etc., with a list of the necessary paraphernalia and a word or two concerning the purpose of the procedure.

The reviewer feels that this splendid volume is a little beyond the comprehension of the average nurse, say for the strictly nursing portions. It might be perused with greater profit by medical students and practitioners because of its academic and practical value.

FRANK E MALLOW

THE ANATOMY OF THE NERVOUS SYSTEM from the Standpoint of Development and Function By STEPHEN WALTER RANSON, M.D., PhD Fourth edition Quarto of 478 pages, illustrated Philadelphia and London, W B Saunders Company, 1931 Cloth, \$6 50

This book, in its fourth edition, continues to maintain its well established primal position in the teaching field of neurology. The reviewer considers it to be the outstanding work on the anatomy of the nervous system. It is a marvel of clarity and simplicity. To the beginner a work of this character is of great value, stressing fundamentals, and avoiding purposefully all confusing details. Too often the subject of neurology (with an emphasis on neuroanatomy) is rendered unnecessarily complex and mysterious whereas because of the almost perfect constancy of its response, its presentation should be simple.

The book is profusely illustrated. These illustrations (341) all carefully selected, being the result of years of teaching experience by a master in this field. Dr Ranson is not only a careful scientific investigator, but an excellent teacher whose enthusiasm is communicated to the pages of his book, instilling vigor into what is often a very dry, abstract subject. It is needless to add that this book is recommended to every student of the anatomy of the nervous system.

HAROLD R. MERWARTH

OUR NEIGHBORS

COST OF MEDICAL CARE IN TENNESSEE

The February number of the Journal of the Tennessee State Medical Association has an editorial discussion on the literature sent out by the National Committee on the Cost of Medical Care, and points out some of the misunderstandings that arise from a study of the report. The editorial says:

"Figures are set up to show that a fairly large percentage of people in a certain community did not receive medical care in a certain period of time. These statements of fact are interpreted to mean that the machinery, or mechanism, by which medical services are delivered to people is at fault. Vital facts pertaining to the whole matter are left completely out of the picture. For example, the report does not show that services were sought and not obtainable. The report shows simply that services were not delivered. They leave out of consideration the fact that a fairly large number of people will not avail themselves of free medical and hospital services when available, nor do they take into account the fact that a fair number of people regard it as a sin to have a doctor at all.

"Another example of the type of thinking: An old estimate of the value of human life arrived at by some sort of statistical analysis is set up as an actual value of human life in the United States. These values are placed in round numbers. According to figures each human is worth \$10,000 and the entire human population in the United States is worth \$1,500,000,000,000.00. The human population includes criminals, the insane, decrepids, in fact, all the people who are a burden to society and not an economic asset at all. No one can dispute this valuation, even though it is many times the value of all other assets combined (placed by experts at \$329,000,000,000). I would not dispute the value of it were it three times the amount stated, because from a personal standpoint there are human values that I rate above all of it, even though their economic worth to me is nothing at all. So to use such arbitrary values as a basis for justifying expenditures is utterly ridiculous.

"We lose sight of the fact that people have sacrificed lives which they themselves would value highly to obtain the thing we call liberty, the value or price of which no one can fix.

"Another example is that one week per year is lost from work on account of illness and the value of this time is set up as a loss to humanity. The fact that there are seven millions of unemployed people ready to take the jobs of those who are

disabled is lost sight of. The disability of one will be the good fortune of another, so the public as a whole does not suffer a loss at all. One individual loses, another individual gains and the work is done.

"All such statistical analyses disregard the most vital and fundamental facts pertaining to human nature, namely, the psychology of humans. The human has ambitions, hopes, desires, prejudices, likes and dislikes, etc., which other animals do not possess. No one can place a value on each of these attributes, still these very attributes make human values.

"The man with a passion for drink is not governed by a statistical analysis dealing with the harmful influence of drink. If the passion follows other lines, figures do not have material influence. If one throws emotions and sentiments to the winds there are many things that have a value which would cease to have a value, so such valuations are nonsense to start with.

"In this report a direct criticism of the medical profession is skillfully avoided, though it is insisted that the machinery by which medical service is delivered is not what it ought to be.

"We don't suppose that anybody would insist that our facilities for medical service are just what they might be, nor can it be insisted that any other human organization in existence is perfect. It can be successfully maintained that in the last fifty years the system of medical service has given a good account of itself. Human misery has been diminished. Human life has been prolonged and some diseases have almost disappeared. All these things have happened under the very faulty system now in vogue, and even before vast sums of money were appropriated for investigations, endowments, etc.

"The general public may read these reports and be misguided by them into attempting to bring about radical changes in our whole system of government, medical service included.

"We must bear in mind that there are people of intelligence now living who insist that religion is all wrong. Others insist that our entire governmental system is wrong and most of these critics are willing to set themselves up as authorities, or dictators, provided they are well financed while engaged in the activity.

"In the Constitution of the United States emphasis was placed on the 'pursuit of happiness' by the individual. A government was set up for the purpose of guaranteeing to the individual the

A distinctively different genito-urinary product

SERENIUM is an azo dye differing in chemical structure from other azo compounds which have been offered as genito-urinary antiseptics. It possesses strong bacteriostatic power even in dilutions up to 1:20,000.

Serenium is non-toxic in many times the usual therapeutic dose. When used in the treatment of pyelitis and cystitis, it frequently alleviates the symptoms and clears up the clinical findings. In gonorrhea, when used together with proper local treatment, it favorably influences the course of the disease.

Because of the widespread acceptance of Serenium Squibb and of the various economies resulting from increased production, it is now available at a greatly reduced price which permits its use by nearly all patients who need this medication. Serenium Squibb is marketed in bottles of 50 and 500 tablets.

THOUGHTS

ON THE PRESCRIBING OF DIGITALIS NO. 1

DIGITALIS is one of the drugs about which a physician cannot be over-particular. When he comes to write a digitalis prescription he cannot afford merely to write "powdered digitalis" or "tincture digitalis" because there is such a wide variation in the digitalis products on the market.

You will remember the old couplet which ran

*"A primrose by the river's brim,
A yellow primrose was to him,
and it was nothing more."*

This is an attitude that the physician would wish to avoid in writing a prescription for digitalis.

When the physician specifies "Tincture Digitalis Upsher Smith" or "Capsules Folia - Digitalis Upsher Smith" he is insured products which have been prepared under the most exacting conditions from the planting of the seed to the final product, with the view of maintaining a high and uniform potency.

Finally, the products are submitted to biological assay, in the laboratory of one of our prominent universities, before and after manufacture, and the strength stated in terms of the International Standard Digitalis Powder.

With the adoption of the International Unit we put one International Unit of digitalis in one c.c. of the tincture and in one capsule or tablet. Note how this simplifies dosage, thus:

- 1 International Unit = 2 grains U.S.P. Digitalis Powder
- 1 c.c. Tincture = 2 grains U.S.P. Digitalis Powder
- 1 International Unit Capsule = 2 grains U.S.P. Digitalis Powder
- ½ International Unit Tablet = 1 grain U.S.P. Digitalis Powder

Full information on the International Unit is supplied in our new booklet "New Thoughts on Digitalis Action and Dosage."

Write for your copy today and for clinical trial package of Upsher Smith Digitalis.

high privilege of pursuing happiness in his own way. The pursuit of happiness has no economic value that one can define, though it is a mighty driving force. One man cannot define for another what happiness is, though there are those who would define it and then put all others in the pursuit of the thing they have so defined. This, of course, cannot be done, but an awful tragedy can be brought about in an attempt to do it.

"Bad thinking is a dangerous thing to follow, no difference who does it."

COST OF "WISCONSIN MEDICAL JOURNAL"

The *Wisconsin Medical Journal* for February contains a report of the managing editor of the Journal, in which he says:

"A financial statement for the calendar year is attached as Addendum B. It is to be noted that the Journal loss for the year was less than \$350 which has been covered by appropriation from State Society funds. So long as the Journal continues to maintain its high standards for advertising, it seems probable that it will continue to incur loss during the current period of economic stress. This might be avoided by reducing the page content but the Board does not recommend this procedure. Over a period of the last six years the Journal has been published without cost to the Society, a record that is equalled in but one or two other states. Even with the added appropriation for improving the Journal as recommended by the Editorial Board, the costs of publication to the membership will still be under that in practically all states publishing like journals."

The editor continues in an addendum:

"The Journal, while owned wholly by the Society, maintains a separate set of books and its own financial set-up that costs of publication may be known at all times, not possible without such segregation.

"The Journal thus pays its share of the rent, of the salary of the Secretary-Managing Editor, postage, supplies, and for its own bookkeeping and annual audits.

"The present report is for the calendar year 1931.

"Income:

"Advertising (December estimated) . . .	\$9,157.09

THE INDIGENT SICK IN WISCONSIN

A system of caring for the indigent sick through the County Medical Society has been tried in several states, especially Iowa. A description of a year's experience of the Polk County Medical Society, Wisconsin, is contained in the February issue of the *Wisconsin Medical Journal*, written by Dr. G. B. Larsen, Secretary of the Polk County Society, as follows:

"On November first, 1931, the Polk County Medical Society concluded one year's operation under the contract system of caring for the indigent sick. We were well satisfied with the system and have no regrets. It was a worthwhile experiment.

"Prior to the adoption of the contract system in Polk County, the members of the Society were wrangling constantly with the poor relief authorities to secure authorization to care for an indigent patient. Oftentimes after procuring authorization it was very difficult to secure payment for services rendered, and if, eventually, payment were obtained, the bill was cut without thought of the services rendered.

"As a group, we have always 'bucked' every type of poor relief advanced by the laity without offering any constructive alternative. By chance we read of the 'Iowa Plan' in the *American Medical Association Bulletin* and from the material received from the Iowa State Medical Society we developed, with the aid of the legal counsel of the State Medical Society of Wisconsin, the contract which appeared in the 1931 June issue of the *Wisconsin Medical Journal*.

"We offered to care for the indigent sick in Polk County for one year for the sum of \$2,500 (the population of the county is 26,000). We de-

An Antitoxic Food Which Changes the Flora

PROVIDE the right kind of "soil" and you encourage the growth of the right kind of bacteria.

Where there is an existing putrefaction, the obvious method of changing the flora is to change the dietary habits of the patient and supply those foods upon which the normal *B. acidophilus* is known to thrive.

Based on the work of Torrey, Kendall, Rettger, Cannon, the two most desirable foods for the purpose were found to be the carbohydrates — lactose and dextrin — first prepared by us to meet physical requirements, under the name

LACTO-DEXTRIN

(Lactose 73% — dextrin 25%)

Lacto-Dextrin offers a drugless, natural way of suppressing putrefaction and intestinal poisons by changing the flora.

Let us send you a physician's sample of Lacto-Dextrin with our compliments.

terminated this figure in two ways: first, by taking the total amount paid for medical and surgical services during the previous year and adding to that the amounts cut from reasonable fees and disallowed bills, and second, we bartered for the highest possible figure we could secure from the committee, having in mind the type of service we were anxious to render to the indigent.

"We agreed to render medical and surgical care (obstetrics excluded) for all indigent patients sent to us by the members of the county committee. The designation of county patients was to be made by the poor relief authorities. We were protected on our major surgical cases with a clause in our contract which made the expense of hospitalization fall upon the county. This acted as a check to prevent the poor relief authorities from bringing unnecessary surgery to the members of the Society. Contrary to the expectations of some members of the Society, the poor relief committee did not ask us to render services to patients that were not worthy of charity, and patients were not urged to take advantage of this free medical service. We found the committee to be very cooperative and in many cases attempted to prevent pauperizing the people by securing some compensation for our services from the patients.

"When the contract was put into effect a schedule of prices was agreed upon by the members of the Society and all bills mailed to the Secretary conformed to the prices agreed upon in the schedule. Bills for services rendered were mailed to the Secretary immediately after the case was dismissed. At the conclusion of the contract the bills for each individual member were totaled and then a grand total of all bills was taken. This final total amounted to \$6,300. The difference (\$3,800) is evidence enough that the indigent sick were cared for well. The expenses of running the Society for the year, the members' dues for the coming year, the secretary's salary and a balance for the coming year were deducted from the original sum received. The balance remaining to be divided among the members allowed a payment of 30.5% of their bills according to the predetermined fee schedule. This was pro-rated according to the volume of work done.

"The result was that we did this work at a price far below a reasonable fee. It was an experiment to solve the question of caring for the poor and, as such, was a success. An attempt to secure a renewal of the contract with the new poor relief group with which we made the contract was discarded by the county board and a different type of county relief instituted. We

Real Comfort in a HERNIA SUPPORT

Perfect retention of the pad plus firm support but with enough elasticity to adjust itself to every body movement, makes this new Camp Belt (No. 44) the most comfortable hernia support on the market. Extra heavy, double weave all-elastic, knitted into groin shape to fit natural body lines and narrow to give it under-abdominal purchase. The peculiar action of the Camp Patented Adjustment operated from the back holds the cup-shaped pad in exact position, preventing shifting and slipping. Perineal straps, also elastic, assist. Adjustable to any degree of rigidity.

Physiological Supports

Sold at all better Drug and Department Stores, Surgical Section, and Specialty Corset Shops. Write for Physician's Manual, Men's Section.

offered a contract for the next year at \$4,500 and later reduced the figure to \$4,000. The poor relief committee refused to go higher than \$3,500 and the members of the Society decided that they could not work for that amount.

"We have been able (through this fund) to develop a constructive public health program. The most practical accomplishment of the public health plan was a county-wide diphtheria immunization program, in which approximately 2,500 children were immunized. The Society has developed a weekly health column and secures space in practically all papers in the county. This was made possible by entertaining the editors at Society expense and discussing our problems. The school clerks, women's organizations and other lay groups have been circularized with health information by direct letters. In short, the laity has come to look upon the Polk County Medical Society as a source of medical information. It would have been impossible to have secured funds for this work by assessment of members, as assessments have a tendency to disrupt any organization rather than uniting it into a whole.

"This fund has united us into a more concrete body ready to meet oncoming problems of organized medicine. There is nothing today that is so evident in the medical profession as the lack of

organization among the county medical societies. The county societies should be so well organized that, at the command of the leaders of the State Society, we would move as a body.

"The Polk County Medical Society recommends the contract system as a means toward that unity."

BUDGET OF WISCONSIN STATE SOCIETY

The 1932 budget of the State Medical Society of Wisconsin is discussed in detail in the *Wisconsin Medical Journal* for February, describing the action of the Council as follows:

"1. Rent. The Secretary reported he had been able to secure a reduction from \$1,020 to \$840.

"2. Supplies, including stationery, postage, miscellaneous printing, telephone, telegraph, office equipment and miscellaneous purchases. The Secretary reported that this cost \$2,900 in 1931 but that \$2,400 was considered sufficient for 1932.

"3. Press Service, furnishing over 300 papers with a weekly service. The Secretary reported that \$2,750 had been budgeted for 1931 of which but \$2,462.88 had been used. The Committee suggested \$2,500. The Council voted \$2,200.

"4. Travel of Secretary and Assistant. Cost in 1931 was \$675. The Committee recommended \$600. (Continued on page 370—adv. xvi)

Colloidal IRON in ANEMIAS

Prescribed in
8 oz. bottles

Dose,
dr. i. t.i.d. p.c.

IDOZAN is a stable colloidal iron solution, NEUTRAL, and contains 5% of iron.

Colloidal iron therapy represents a significant advance over the old iron preparations.

IDOZAN is an active iron preparation which will produce a definite rise in the hemoglobin in cases of simple anemia, chlorosis, secondary anemia and post partum hemorrhage.

IDOZAN makes "new blood," better blood; thus acting as a dependable "iron tonic."

Each teaspoonful contains 5 grains of Iron.

"5. Editorial Board. This item was budgeted at \$2,500 for 1931 of which \$1,000 was used. \$1,500 was voted.

"6. Annual Meeting. \$1,831.01 used in 1931. \$1,800 suggested for 1932.

"7. Committee on Public Policy. 1931, a legislative year, expenses \$2,124.08. Committee recommends \$500.

"8. Hygeia, 275 subscriptions. Council approved continuation of \$500 for this item at September meeting.

"9. Delegates to A.M.A. Rail and Pullman fare only. \$245.01 used in 1931. Committee recommended \$240 for 1932.

"10. Secretaries' Conference. Held in April, 1931, at expense of \$819.71. To be held in connection with Annual Meeting in 1932. Committee recommends \$300.

"11. Legal advice and opinions. Expenses in 1931 were \$697.75. Recommended for 1932 is \$600.

"12. Committee and Council meetings. Expenses in 1931 were \$262.62. Recommended for 1932 is \$400.

"13. Committee on Cancer. Expenses in 1931 were \$500. No appropriation needed in 1932.

"14. Foundation Fund. Appropriation in 1931 was \$600 of which \$225 was used. Recommended for completion of work in 1932 is \$250.

"15. Special Committee to Study Distribution of Medical Services (authorized by House of Delegates).

"16. Revision of model constitution and by-laws for component county societies, \$100.

"17. Treasurer, Honorarium, \$300. This honorarium goes to the accountant who handles the work of the Treasurer. Same amount as in 1931.

"18. Miss Florence Ripley and Miss Elleanor Beck, assistants in the Secretary's office. Presently receiving \$1,680 each. Secretary and Committee recommends \$1,700 each.

"19. Miss Ruth Buellesbach, assistant to the Secretary. Under contract for 1932 at same amount as 1931—\$2,100.

"20. Mr. J. G. Crownhart, Secretary. For the years 1930 and 1931 Mr. Crownhart has received \$6,800 from the general funds of the Society and \$1,200 from the Journal, totaling \$8,000 a year. Council votes to continue salary for 1932 at same figure."

These items were adopted by the Council.

MEDICAL EXAMINERS IN COLORADO

Colorado Medicine for February contains the proceedings of the Colorado Board of Medical Examiners, with the following explanatory note:

"The Colorado State Board of Medical Ex-

(Continued on page 371—adv. xvii)

(Continued from page 370—adv xvi)

aminers has kindly offered to supply *Colorado Medicine* with a digest of such of its quarterly proceedings as are suitable for publicity, and we are pleased to present herewith the digest of the first 1932 meeting

"The Board of Medical Examiners met on January 5 and 6 and considered nine applications for licenses to practice medicine, eight applications for licenses to practice chiropractic, eight complaints for the revocation of licenses of chiropractors, and one complaint for revocation of the license of a doctor of medicine

"All of the applications for licenses to practice medicine or chiropractic were granted. Two of the medical applications were for reinstatement after revocation. All but one of the medical applicants had previously been licensed in other states and were licensed in Colorado on credentials

"Of the eight complaints before the board against chiropractors, the Board had time to take evidence in only five cases. All of these resulted in revocation of license. In four of the five cases the chiropractors had been using electric therapy in various forms, in the other case the chiropractor had been injecting an autogenous serum which he prepared from the blood of the patient, another autogenous preparation made from the urine of the patient, called the 'autobiochemic treatment,' and had been treating cancers with Koch's Cancer Cure

"The chiropractor last mentioned testified that he was assisted in his work by a doctor of medicine, who is a member of the Pueblo County Medical Society. This doctor of medicine testified that he was a medical director of two institutions in Pueblo and that his services consisted of diagnosing cancer and prescribing the treatment therefor. At chiropractor's institution he diagnosed the cancers and prescribed Koch's Cancer Cure. At the other institution he diagnosed the cancers and prescribed the proprietor's cancer paste, although the proprietor had no kind of a license to practice the healing art in Colorado. This doctor of medicine readily admitted that he did not know the formula of either remedy which he prescribed. Besides revoking the chiropractor's license to practice chiropractic, the Board ordered that the doctor of medicine who was assisting him be given a thirty-day notice of hearing at the next quarterly meeting of the Board

"The medical license of Dr. Benjamin Replogle, M.D., of Fort Collins was revoked for unprofessional and dishonorable conduct

"Numerous other matters came before the Board for consideration, some resulting in resolutions ordering licensees to appear at the next meeting for hearing on the revocation of their licenses, and others resulting in private censure without the institution of formal disciplinary proceedings

"LET'S TAKE OUR

CRIPPLED CHILDREN IN ILLINOIS

An editorial in the February number of the *Illinois Medical Journal* describes the system of clinics for crippled children conducted by the Warren County Medical Society, as follows:

"The Warren County (Illinois) Medical Society is just starting its sixth year of Crippled Children's Clinics, and the plan of operation of this successful clinic is worthy of the attention of other societies.

"The clinic is held regularly, at the City Hospital in Monmouth. All of the hospital authorities are interested in the welfare of this community, and cooperate thoroughly with the local Medical Society to see that there is no lost time, and no overlapping of effort in arranging, and conducting the clinics.

"All patients are received at the hospital, entered properly on the records, and given a number, which is not changed in succeeding clinics. The records are kept in cumulative form, each patient's records being kept in the files in a separate folder. This folder contains the history of the case, a report of the original examination, and the recommendations of the clinician. At succeeding clinics these records are ready for the clinician, with a report of the follow-up services, and eventually, a complete record of the case as seen at subsequent clinics, is a part of this cumulative record. One copy of the record is given to the family physician of each case, one copy retained on file at the hospital, and a third copy is given to the visiting nurses. Two nurses, a County nurse and Welfare nurse, a few days following each clinic, call at the home of the patients, to be sure that the instructions given were understood, and later, carried out. This is a most important feature of this routine. The Warren County Medical Society has used the same clinician for all of these clinics, and with the system which has been gradually established, it is possible to see twice as many patients now, in a day, as were seen in the earlier clinics. The family physician of each case is urged to be present, and hear the advice given to the parents, so that they will be able to give a thorough cooperation, for the best interests of the patient.

"It is not difficult to convince the people of the community that all clinics should be conducted entirely under the supervision of medically trained people, in order that they may receive the maximum benefit. How can the necessary financial assistance for clinics of this sort be arranged? For several years, it has been the custom in Warren County, for a local lodge to sponsor 'The Annual Charity Ball,' the receipts to be used for the crippled children's work. Sufficient funds have been received to more than pay all expenses, and give a decent working fund for future use.

"What has been done in Warren County, through the efforts of the local County Medical

Society, can likewise be done in other counties in Illinois. It is our opinion that all other clinics can be arranged along similar lines, so that it will not be necessary for any Lay Organization in Illinois to assume leadership in the conduct of any type of clinics in the near future."

THREE GENERATIONS OF IOWA PHYSICIANS

The NEW YORK STATE JOURNAL OF MEDICINE has recorded several examples of three generations of physicians in families, but these examples have been surprisingly small. The February number of the Journal of the Iowa State Medical Society devotes a page to three generations of physicians in the Neal family.

Dr. Benjamin G. Neal was born in Missouri in 1825 and learned the trade of a printer. He practiced in Columbus City and Fort Madison. The article says:

"He continued to follow his vocation as printer in connection with the practice of medicine, and it is reported that he walked to Iowa City in 1850 to secure employment with the printer in setting type on the first Code of Iowa. . . . It is reported that Doctor Neal performed the first Cesarean operation west of the Mississippi River. He was intimately associated with Dr. James M. Robertson, and it stated that when sickness was very prevalent, the needs of the afflicted patients of each in their great territory extending over Louisa, Washington, Johnson and Muscatine counties, were served by alternating trips of the different routes, administering to each other's patients. He died at Fort Madison in 1898 at the age of 73 years, having completed nearly 50 years of pioneer practice in Iowa."

Dr. George P. Neal, his son, was born in 1852. "For sixteen years he practiced medicine with his father, Dr. Benjamin G. Neal. While located at Columbus Junction, Doctor Neal was editor of the *Louisa County Times* for two years, and was also postmaster under Cleveland's first administration. He moved to Fort Madison January 1, 1890, and continued to practice there until his death July 12, 1930."

Dr. Emma Jewel Neal, was born in 1878, and now practices in Cedar Rapids, and is actively interested in all forms of civic medicine.

The account concludes:

"The three generations of Doctors Neal have thus far covered a period of practice in Iowa of eighty-three years, which is indeed an enviable record."

Professional Samples Free

PHENO-COSAN promptly
relieves skin troubles . . .

PHENO-COSAN was primarily formulated for the treatment of eczema. In this condition, clinical reports show consistent success.

In addition, physicians report gratifying results in Tinea, Tinea Phytosis and Impetigo Contagioso.

PHENO-COSAN has a vanishing base and requires no bandages. Contains no mercury and is of special value in infant cases.

It is regularly supplied to U. S. Government, State and Civic hospitals.

METRAZOL AS A STIMULANT DURING SURGICAL ANESTHESIA

Metrazol as a Stimulant During Surgical Anesthesia.—(Strasser, an-
esthetist at Deaconess Hospital, Cin-

cinnati) (*Ohio State Medical Journal*,
nal, February, 1932).

"When any of the danger signals of anesthesia, among them irregular breathing, rapid pulse, marked fall of blood pressure, and dilatation of the pupils appear, one must be prepared to act promptly. An efficient cardiac and respiratory stimulant in such crisis often spells the difference between recovery and death of the patient. No anesthetist, in fact, unless he or she were irresponsibly reckless, would dream of giving an anesthetic to a patient unless proper stimulants were at hand for any emergency which might arise. . . .

"We believe such a stimulant has been found in Metrazol (pentamethylentetrazol). It certainly gives clinical results. Its action on the patient can be seen almost immediately after subcutaneous injection. The respirations become regular and deeper—the pulse slower and the blood pressure rises. Usually cyanotic conditions are promptly relieved. Also the reaction is not over in a few minutes as with camphor, but lasts a half hour and usually longer. Several times we felt an injection of Metrazol was all that saved the patient from death. . . ."

Of the cases in which the effect of Metrazol was observed nine are given as typical of the group. Upon cardiovascular or respiratory distress during operative procedure Metrazol was injected subcutaneously or intravenously, 1 or 2 ampules, and repeated as indicated. Referring to these case histories the author writes: "These few clinical experiences may serve as examples of the value of Metrazol in our hands. We feel that in these cardiovascular emergencies we obtained better results and with greater certainty of effect with Metrazol than we had achieved previously with other stimulants used under similar conditions."—See page xviii.—Adv.

LILLY RESEARCH LABORATORIES

Lord Lister, experimenting with crude carbolic acid as an antiseptic in surgery in 1867, found that in avoiding the danger of infection he was encountering a new difficulty in superficial sloughing and death of tissues. In his paper on "The Early Stages of Inflammation" (1853) he had shown that the effects of irritation on the tissues are twofold: first, a dilatation of the arteries, developed through the nervous system; and second, an alteration in the tissues on which the irritant acts directly.

Capacity to destroy bacteria is a claim that can be made for many modern bactericidal agents even in very high dilutions. Agents that

will accomplish the desired results, however, without injury to animals and animal tissues are comparatively rare.

From the Lilly Research Laboratories comes an interesting announcement of an organic mercurial compound, Merthiolate, said to compare favorably in bactericidal efficiency with the best of germicides now available and to be particularly distinguished by its extremely low toxicity to animals and animal tissues. The literature on Merthiolate states that the product is potent in the presence of organic matter, non-toxic and non-hemolytic for red blood-cells, non-irritating to tissue surfaces, non-staining, and stable in solution. Merthiolate should find a large field of usefulness among medical men. See insert.—Adv.

AN OPPORTUNITY TO EARN \$15,000

Mead Johnson & Company announces an award of \$15,000 to be given to the investigator or group of investigators producing the most conclusive research on the Vitamin A requirements of human beings.

Requirements

Candidates for the award must be physicians or biochemists, residents of the United States or Canada who are not in the employ of any commercial house. Manuscripts must be accepted for publication before December 31st, 1934, by a recognized scientific journal. Investigations shall be essentially clinical in nature, although animal experimentation may be employed secondarily.

Committee on Award

The Committee on Award will consist of eminent authorities who are not connected with Mead Johnson & Company, the names of whom will be announced later.

Source of Supplies

There are no restrictions regarding the source of Vitamin A employed in these investigations.

For other details of the Mead Johnson Vitamin A Clinical Research Award, see special announcement, pages 14 and 15, in the *Journal of the A. M. A.*, January 30, 1932. See page xxiv.—Adv.

CREST VIEW SANATORIUM

Charmingly located, beautifully appointed; in the hilly country one and a half miles from Long Island Sound where the air is tonic. Truly homelike no institutional appearance. See page xxi.—Adv.

JUDGMENT IN GYNECOLOGICAL PROBLEMS*

By GEORGE B BROAD, M D, SYRACUSE, N Y

VIRCHOW once said "Nine physicians out of ten know what to do in a given case and the tenth knows what not to do, and he is the most valuable of the ten" We may not entirely agree with the above but the implication is that judgment was used in the final decision

A word concerning judgment in general before it is applied to the subjects discussed in this paper We often speak of an individual as being a person of good judgment What do we mean? To me good judgment is possessed by the individual who has the ability to draw correct conclusions when all the facts are submitted In other words, it is not knowing facts only, but deducting proper conclusions from facts It comes close to the realm of the practical

All people are said to use one of three kinds of judgment First, impersonal judgment, which in the above sense is not judgment at all for as the term implies, it simply consists of taking the opinion of others Such a person has no opinion and, therefore, no judgment This group is not inconsiderable

The second is known as reflective judgment This again requires the person to obtain the facts and after reflection draw proper and correct conclusions It is easy to see how these two forms include many subdivisions as the individual leans toward the impersonal or reflective type

The third is the intuitive judgment which permits a decision to be reached through the sub-conscious mind, the individual using it not consciously going through a reasoning process It is used by those possessing a background and is considered the highest type of judgment The young surgeon in the beginning must use impersonal judgment As he progresses he should more and more use the reflective and intuitive types of judgment

The first subject I would like to discuss is

simple lesions of the cervix No apology is offered for bringing to your attention some of the simple and common lesions we are called upon to treat This is a period of preventive medicine and surgery It seems to me much more can be done to prevent or correct if present, the number of lacerations and extensive erosions observed Can we by early care and treatment lessen the ever increasing number of cancers of the cervix or if cancer seems remote, can we relieve many a young patient of an annoying and troublesome cervical discharge? Cancer may not be as remote as we sometimes think, for we are seeing cancers in the young comparatively frequently The prevention of lacerations belongs largely to the obstetrician, and I am glad to say we see fewer extensive lacerations in patients who have been skillfully delivered I am under the impression that more primary repairs of the cervix are being performed than ever before and properly done must result in much relief and protection to the patient I would like to quote a statement at this time from the experience of Dr J B DeLee, who advocates frequent primary cervical repairs In twenty years he has not observed a cancer of the cervix following primary cervical repair This, of course, does not mean that they have not occurred but cervical cancer must be infrequent under such conditions I am not competent, not being an obstetrician, to pass upon the universal application of this procedure, but, as a cancer prevention measure it seems effective

Not all women can be delivered by obstetricians and we will still see lacerations and erosions It is a pretty well established fact that the columnar epithelium of the cervix does not thrive when exposed to vaginal secretions Endocervicitis and erosions result from such evasions

In the young we hesitate to advise radical surgery for cervical repair when more children are likely to follow in the near future, but we have in the cautery a means of correcting many

* Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse, N Y June 2 1931

of the erosion and endocervicitis problems. Not only do we lessen the possibility of malignancy but we add much to patient's comfort by stopping an annoying and troublesome discharge. When childbearing is ended, a proper cervical repair should be advised if at all indicated. This advice I am giving with increasing frequency. If surgery is not indicated, lacerated cervixes should be cauterized and made safe from future malignancies. These measures, while not new, need to be re-emphasized in the strongest terms. Who knows to what extent cervical cancer might be prevented if all cervixes were made normal following childbearing? It is possible this dread disease might be lessened to one-half or even one-third of the present number.

One word about cervical erosions in the young girl. The cause has not been fully established. Most authorities attribute such erosions to friction of cervix against the vaginal wall. A few think a low grade infection responsible. Many of these erosions occur in patients below par, the pelvis participating in the general low tone. Local treatment is not usually indicated. It seems rather too bad to submit such patients to pelvic examinations and treatment. Constitutional measures should be instituted. In case of failure to give reasonable relief, the worse cases may have the erosion gently curetted and attempts made to correct friction. I doubt if the cautery is often indicated in these young patients.

The senile cervix rarely gives trouble, excepting, of course, malignancy. Polypi are found, but no difficulties are encountered in their diagnosis and treatment. Occasionally a scant but very annoying discharge is present with itching the most outstanding symptom. The discharge consists of some secretions from cervical glands and a considerable amount of desquamated epithelium. If satisfactory drainage is established this discharge and itching can be reduced and patient made comfortable.

The atrophied cervix and the shrunken atrophic senile vagina do not stand instrumentation and treatment well. If disease is absent and drainage for secretion is established, little more should be done.

Vaginal Plastic Surgery: It has been said with much truth that the character of plastic surgery done by the gynecologist is an index of his surgical ability. Good plastic work is not easy. It requires knowledge of defects in fascial planes and patient painstaking care to correct them. If certain principles are followed results should be satisfactory. On the anterior wall, defects can usually be corrected if fascia at cervico-vesical junction be adequately secured and fascia under bladder re-

paired. It does not greatly matter whether you use the method of Ward or your own, but it must be properly done. The same principle applies to the posterior wall. It seems to me best to consider defects of the posterior wall as a true hernia and the rectal wall as far as need be secured behind a fascial repair. When this is accomplished and the repair is secure, again it does not greatly matter whether the technique of Clarke or Graves or your own is followed, but it must securely correct the defects.

One added precaution must be considered. Irregularities along posterior wall or narrowing at introitus should be avoided. Atrophy at the menopause or over correction has made many a good repair defective, causing worry to both patient and surgeon.

I would like to add one other word. In doing plastic surgery, do not hurry. I think it was Cullen who said the gynecologist who hurries with his plastic work is self-conscious. Do not be troubled if the general surgeon in the next operating room is through with his flap-splitting operation in less time than you. The result in one or five years is the real test. Many times I have seen our best gynecologists take more time with their plastic work than with an extensive abdominal operation.

Pelvic Tumors: Differential diagnosis of pelvic tumors is usually not difficult. Sometimes it taxes the skill of the experienced. This is especially true if complications exist. In small growths if the uterine body can be outlined and the pathology built up around it, the difficulties lessen. If the small tumor springs from the uterus or changes its contour, it is usually a fibroid. If it moves with the uterus even though uterine contour or size seems unchanged, consider a pedunculated fibroid. If the uterus can be surrounded and found unchanged and the tumor is at one side of uterus or behind, consider a cyst. The age of the patient helps somewhat. Please remember these simple rules do not include an attempt to diagnose disease of tubes such as hydrosalpinx, ectopic pregnancy, adenomyoma, endometriosis, etc. Fibroids are very rarely found before twenty-seven or twenty-eight; cysts not infrequently in the young. Large uncomplicated fibroids usually give but little trouble; large cysts are not quite so easily diagnosed although careful search usually reveals a uterine body pressed anteriorly on one side, overriding the cyst. Larger tumors lifted out of the pelvis should rarely cause trouble. Intraligamentous fibroids and cysts are more difficult but the same rules in the main apply. The consistency of the tumor is often helpful. A paper of this kind cannot consider complications such as torsion, infec-

tions, etc. The chief thought in diagnosing pelvic tumors is to find the uterus. If this can be done differential diagnosis will be made easier.

Management of Uterine Fibroid. Judgment in the management of fibroids must be influenced by the size and position of the growth. Other factors include the social condition of the patient, i.e., her desire for children, her general health and her age. In borderline cases, the natural tendencies of the surgeon toward radicalism or conservatism will influence decision. This is the human element, apparent not only in pelvic surgery but in all surgery where fixed standards have not been universally accepted.

The conservative gynecologist would reason something as follows: Small fibroids the size of a plum or smaller if not too numerous, should be removed by myomectomy in the young, say twenty-eight to thirty-five child-bearing function being preserved. Where fibroids are numerous and invade the uterine body, myomectomy is likely to be a futile procedure. Even under such conditions early hysterectomy in the young is not favored at this stage if no symptoms result, which is the rule if fibroids are subserous. Many a child has been born with the mother having subserous or intramural fibroids without undue risk to mother unless fibroids grow from the lower uterine segment. With submucous or interstitial fibroids near uterine mucosa, it is a different matter. The probability of impregnation is lessened in a fibroid uterus, or if it occurs, abortion is much more likely to happen. Hemorrhagia is quite likely to force treatment.

Small fibroids between thirty-five and forty-two and three should be watched. If they do not grow and are not causing symptoms they need only be watched. If they grow, change their characteristics or are causing symptoms they should be treated by methods suggested later. Small fibroids from forty-three to fifty usually require no treatment, if symptomless, although there are exceptions to this statement. It should be remembered that women with fibroids as a rule menstruate longer than women without fibroids. Later changes and degeneration can occur. This should be kept in mind and those patients treated as the individual case demands.

It is more difficult to lay down rules for fibroids as large as an orange. Possibly in young patients with but a single fibroid myomectomy might still be the proper treatment. More often a partial removal of uterine body containing fibroid if it occupy the upper part, or a hysterectomy should be advised, retaining ovaries with proper blood supply. In the

latter part of menstrual life a fibroid no larger than an orange can often be satisfactorily treated by radiation, either x-ray or radium. Fibroids larger than an orange or small grapefruit at any time during the menstrual life should be removed by hysterectomy, unless there is some definite contra-indication. This was the rule laid down by Dr. John G. Clarke and is still followed by his associates. His decision was based upon a large experience, with surgery, radium and x-ray at his command. The degenerative changes in large fibroids as well as other complications were numerous enough to make removal the conservative treatment. A recent review of the work of Drs. Norris and Keen at University of Pennsylvania in the treatment of larger fibroids, has added weight to the soundness of his teaching. An attempt has been made to discuss this question conservatively. A radical surgeon could justify a more active course. What should be done with the ovaries is still debatable. In the young I still leave them or one of them. I find myself, however, removing ovaries with greater frequency in the latter years of menstrual life. The frequency of sarcomatous change in fibroids is still in dispute by pathologists. In a series of one hundred of my own cases reviewed some time ago, there seemed to be two unquestioned sarcomas. An infected fibroid is a most serious problem, one which endangers the patient's life.

Ovarian Cysts. The general remarks made earlier on pelvic tumors cover pretty much all I wish to say concerning diagnosis of ovarian cysts. If complicated by torsion the acute symptoms usually give the key to diagnosis. Intraligamentous cysts may require differential diagnosis but this can usually be done. There is but little need for the exercise of judgment in treating ovarian cysts for they should be removed if we except the small follicle cysts. I especially wish to emphasize the need on the part of the surgeon of sufficient knowledge of pathology to act wisely for patient's best interest. He should know that the large pseudo-mucinous cysts frequently have papilloma, potentially malignant. He must appreciate that rupture of such a cyst exposes patient to possibility of transplants of papilloma if they exist. He must also know rupture of pseudo-mucinous cysts may result in a myomatous peritonitis which ends fatally. He should know that the serous cyst adenomata usually have papilloma if at all advanced and that rupture of such a cyst is a serious matter. He should know that the serous cystadenoma tends to occur bilaterally although not simultaneously, and the other ovary cannot be ignored. He should be conscious of the very irritating content of the

dermoid and the greater tendency of peritonitis in case of accident. I have mentioned enough to show the need for fundamental knowledge of pathology on the part of the operator who assumes the responsibility for doing surgery of this character.

The exercise of judgment comes into play when one finds a serous cystadenoma with extensive papillomatous infiltrate. Will one be content with simply removing the cyst, or will one remove the other ovary or even do a hysterectomy to make the patient more secure? If the pathologist reports evidence of malignancy in the papillomata there can be no question. Radical work should be done. If the patient is young and childbearing is important, in simple cases of serous cystadenoma with papilloma, the other ovary may be preserved, trusting the patient to report for observation at frequent intervals. The frequency of malignancy of ovarian cysts and malignancy of the ovary has been a source of increasing anxiety.

Uterine Displacements: Few conditions in the female pelvis require better judgment in their management than uterine displacements. This applies to uterine retroversions in particular. In the main certain principles apply. The first query is, does the displacement cause symptoms? If so, are the symptoms sufficiently severe to require radical treatment or will simple methods better serve the patient? In many cases this can be determined in the office. If the uterus is replaceable, a proper fitting pessary is a great help. This is not the time or place to dilate upon the use of the pessary. It is often misused. Its principle is fairly simple. If the pelvic symptoms, i.e., pressure, bearing down, etc., and backache, are relieved by replacement with pessary over several weeks' observation, one is justified in assuming that the displacement is causing the symptoms. Even so, shall operation be universally advised? I believe not. The age, desire for more children, social condition and whether or not the displacement is part of a general ptosis as well as many other factors should be taken into account.

Displacements of uterus in the young woman in her 20's who desires children, or more children, may well be carried along for a time with a pessary, hoping for an early impregnation. Should pregnancy occur, one may reasonably expect the uterus to be lifted from its displacement by the developing pregnancy. Rarely is manual help necessary. On occasions the knee chest position, gentle force or a pessary may be used. The responsibility after confinement shifts to the obstetrician. I have long felt much could be accomplished if special attention be given patients while

recovering following confinement, if uterus retroverts.

When the uterine displacement has been proven to be the real cause of symptoms sufficient to impair the health or happiness of the individual replacement is indicated. Surgical procedures in the main should be followed. There are still a few exceptions. Most workers in gynecology have had now and then a patient much below par in general health with a moderate retroversion replaceable. These patients with uteri held in place by a proper pessary have gained in general health and strength. We have all been gratified to find uterus remaining in place after pessary has been finally removed. While a few of these patients may be permanently well, one never feels quite safe. Should poor health or pregnancy recur, their uteri are unstable.

The surgical operations for overcoming the displacement are dependable. It does not greatly matter which operation one does if it is applicable to the case. Earlier our lists revealed a tendency to use the principle evolved by Gillman, modifying his original technique by securing the round ligaments at or near the internal ring. Several operators have their names attached to this modification. Latterly, we have more frequently used the Olshausen suspension. Whatever operation is selected, circumstances may vary its application. We have all seen the results of a suspending operation where the uterus was attached low or to a weak abdominal wall, which permitted the cervix to descend so low the results were very unsatisfactory. The selection of the proper patient for operating in cases of uterine retroversion, I wish to again reiterate is of the greatest importance. Replacement operations performed upon patients just because they have a displacement of uterus is to be condemned.

Never attempt to use a pessary where marked retroflexion is present. It is not replaceable by this means.

Backache as a symptom in uterine retro-displacement has received and deserves much attention. Low down central backache is the type of backache associated with uterine displacement. The proof of its pelvic origin is in relieving the backache by replacing uterus. Backache of the lumbar type is usually of extra pelvic origin.

Retro-displacements of the uterus are usually simple to diagnose. The condition most frequently confused by the inexperienced is a retrocession with an antelexion. This error can be obviated if the principle laid down earlier in this paper is followed, viz: locate the uterine body. If this is done, the backward bend of the cervico-corporal portion will not

mislead. After careful search the uterine body, usually small, can be found anteriorly. Retrocession with antelexion is apt to be associated with defective uterine development.

Uterine Prolapse. Uterine prolapse is easy to diagnose if at all advanced. It can be recognized in its early stages. Perhaps the term uterine descensus could more appropriately be used. In the beginning weakness of the anterior wall particularly at the cervico-vesical junction should be recognized. The uterine axis is usually in line with vaginal axis or utero retro-displacement is present. These changes with low placement of all pelvic organs are indications of impending prolapse. It has always seemed good judgment when the above physical signs are present to correct them unless there is some good reason for not doing so. Possibly the reason under these conditions for not urging repair when there are few symptoms rests in the fact that no one can tell to just what extent the descent will continue. This may be good reasoning for the time, but it is a better policy if operation does not seem indicated at once to keep such a patient under observation. If there is definite increase in descent while such a patient is under observation operation should be advised. It will be much simpler to do satisfactory plaster surgery before uterus and bladder have descended to second or third degree. The condition of the perineum has not been mentioned among early indications. At this stage it is of much less importance. A relaxed and torn perineum when descent is well under way must make it easier for all the pelvic organs to prolapse and conversely a good perineum often retards downward progress in some cases. The perineum, however, cannot be considered as playing a very important role early in uterine prolapse. Much more important is the tone and strength of the uterine cardinal ligaments. The symptoms do not need to be considered except to mention the early drag and bearing down which comes when structures of vaginal vault begin to weaken. This is again a warning. Treatment is surgical for most satisfactory results. The methods adopted depend upon surgeon's experience, ability and judgment. The plastic surgeon can obtain fair results in many cases by plastic surgery alone if he sees his cases early and he has good tissues to use. In most of the advanced cases more than this is required. Whether you do a Mayo hysterectomy a plastic with abdominal fixation or suspension or a Watkins interposition will again depend upon your experience and ability. Three years ago I reviewed one hundred cases of uterine prolapse before this section and my analysis showed I had used all four methods in this series. I tried to adopt the method best

sued to the individual case. The results in the main were satisfactory. My results were least satisfactory with the Mayo method, probably because my experience with this operation has not been extensive.

If operation is not to be considered, the Gehrung pessary is if usable, an aid in holding up the uterus and making the patient more comfortable.

Pelvic Inflammation. Pelvic inflammation is still very common and not difficult to diagnose. Its treatment is pretty well established along fixed lines. Individual judgment is still necessary in course finally followed. Early operative work can be justified only as a relief measure. Extensive exudate containing pus in moderate amount, recover better without surgery. Large amounts of pus usually need drainage. The advice after the attack carries with it definite responsibility. It seems to me one is justified in awaiting developments in a young woman if the exudate absorbs. Should the organ be bound down giving evidence of permanently crippled pelvis, not much is gained by deferring surgery after patient is ready. Should the infection relight, there is little hope of function being restored or patient returning to health. Operation under these conditions should be advised when patient is ready. The operation on tubes should be complete removal. Any attempt to save isthmus even though it seems open is usually futile. Ovaries are more resistant because of their thick tunica albuginea. Despite this the life of the ovaries is frequently very much impaired by the surrounding infection, their blood supply diminished and they function poorly. Unless some unusual reason appears for conserving them, they are best removed. This decision may not apply to the very young. At the Syracuse Memorial Hospital one of our services is again trying to transplant the good portions of the ovaries in the rectal sheath. I hope we may be able to obtain enough encouragement from this work to make it worth while. Dr. Graves believes in most cases the uterus too should be removed. I have not universally done so, perhaps less frequently than I should. My reason for leaving the uterus, especially in the young, is that it is not the seat of active infection as a rule. The gonococcus does not usually invade the endometrium. It is the bridge over which this mischief maker is carried from the cervix to the tubes. It is most exceptional to find foci of infection of g.c. type retaining virulence in the myometrium. If it seems wise to save one ovary or a part of one, menstrual function can for a considerable time be preserved. For this the young patient is usually grateful. In more mature patients from thirty-five on, if the future of the patient

is more secure, the pelvic organs including uterus may well be removed.

We are waiting longer after an acute attack before advising operation in the operable group. The patient is profiting. Our mortality and morbidity are lessening. We have better guides. Three weeks of normal temperature and normal leukocytosis should make surgery reasonably safe. Now we have red cell sedimentation to further help. A two hour sedimentation adds much to patient's security. One and one-half hours makes patient reasonably safe.

The term pelvic inflammation refers only to g.c. and not to obstetrical infections, the former producing an endosalpingitis, the latter a perisalpingitis, with a much better outlook for functioning tubes.

Uterine Cancer: Judgment in management of uterine cancer should be simple. The diagnosis of cancer of uterus is another matter. We must continue to talk in season and out of the need of having every case of irregular uterine bleeding explained. If women and family physicians could realize that probably every woman who begins to bleed after menopause has been established in all reasonableness has a beginning malignancy, many lives could be saved for we are curing, and I use the word advisedly, early cases of uterine cancer. It is a temptation to discuss what is being done in trying to separate types of cancer by cell differentiation. It may lead to help in prognosis, but, whatever the type of cell, not much can be expected when the invasion has gone beyond the reach of the remedial agent, be it radium or surgery. Most of you are well aware we are not operating cervical cancer except in very rare instances. You also know we are advising complete surgical removal of uterus in cancer of uterine body if at all operable, either before or after the use of radium. The responsibility of the family physician or the one who first sees the patient is very great. Irregular uterine bleeding is the most outstanding symptom of cancer either of cervix or uterine body. If its significance could early be appreciated, what a difference it would make. Of course, it would still be better if the very early serous discharge could be correctly interpreted. This is perhaps asking too much. Post-menopause bleeding should in every case

be considered malignant, until proved otherwise. It has been my policy in recent years to take the physician who honors me with his consultation aside, if he has made a mistake, and go over the case in detail, pointing out his error in interpretation of symptoms. I do this in the kindest way, for no doctor of my acquaintance would knowingly give poor advice to one who trusts him or her. This helpful review sometimes causes chagrin, never has it caused resentment. The not uncommon method when I began practice was for the consultant to comfort the doctor who made an error in diagnosis by pointing out some of the unusual features by which he was misled. It is poor comfort to the doctor or patient. I am sure if all consultants took time in all surgical problems where there has been delay, to help the physician to see where he could have arrived at a diagnosis sooner, it would be better for all concerned, particularly the patient.

I mentioned earlier the need for recognizing senile changes in the vagina and their careful management. I would like to comment upon changes in the vulva, largely of a senile character. The outstanding change is kraurosis vulvæ, one of the most annoying and tormenting of vulvar afflictions. It does not seem to be so troublesome in very late life as in the 50's and 60's, not infrequently in the late 40's. Atrophy, of course, is the most apparent physical sign, but itching is the symptom which drives them to the physician. It may be and probably is caused in some way by the lessened or absent secretion from the ovaries but supplying this artificially has done but little good in my hands, although Graves thinks he has obtained results at times. Kraurosis vulvæ is mentioned because of the increased possibility of malignancy. Leucoplakia must also be closely watched. The number of malignancies following this change is very disquieting. In two outstanding instances recently have I had a report of malignancy returned after removal of small atypical lesions. By early radical removal, I hope I have made more secure the future of these patients. It would seem wise to remove any area on slight suspicion doing as radical work as evidence justifies. We all know the very serious, almost hopeless outlook in carcinoma of vulva if the disease is at all well established.

VOLKMANN'S CONTRACTURE OF THE LEG

By EDWARD K CRAVENER, M D, SCHENECTADY, N Y

CERTAIN entities in medicine have become inseparable interstitial keratitis and lues, gumine and malaria, liver and pernicious anemia. Similarly, the reaction word to Volkmann's contracture is forearm.

Volkmann's contracture need not occur in the forearm alone. By its accepted etiology, it can occur in any region where the blood return can be obstructed and engorged muscles be constricted by strong fascial planes. The original articles do not confine this lesion to the forearm. Richard Volkmann,¹ writing in 1881, mentions the occurrence of this disorder in the lower extremity. Dean Lewis² mentions this condition as occurring after fractures of the lower end of the femur. Alfred Taylor³ states in discussing this condition "that only cases occurring in the upper extremity will be considered," indicating recognition of cases in other parts of the body. Meyerding⁴ in reporting one hundred and twenty-eight cases from the Mayo Clinic, mentions three contractures following fractures of the tibia and fibula. In his summary he states that over ninety per cent of these contractures occur in the forearm. Paul Jepson⁵ states "in the majority of cases, the injury is in the upper extremity."

In this short paper, no attempt is made to outline the etiologies variously ascribed for this condition. I believe the consensus of opinion, since the work of Brooks⁶, is that by pressure or some other mechanism, the return venous flow is diminished and the muscles become engorged with blood and transudated serum from the damaged capillaries. This extravasation is limited, early, by fascial planes surrounding the muscle bellies. As the condition becomes more intense this capillary oozing pushes on to involve other muscles and to surround the adjacent nerves. Later these nerves may be bound down by organization of the adventitious blood and true nerve lesions result. One author⁷ believes that an unhappy combination of circumstances, engorgement, embarrassment of the venous return and diminished arterial supply cause scarring with consequent contracture.

There is basic similarity in the anatomy of the volar surface of the forearm and the posterior aspect of the leg. In the forearm the flexor profundus and the long flexor of the thumb lie just ventral to the interosseous membrane of the radius and ulna, and are surrounded by the extension of the antebrachial fascia and overlain by the bellies of the superficial flexors of the fingers and wrist. In the calf, the posterior tibial and long flexor of the toes occupy an exactly similar position in relation to the interosseous membrane of the tibia and fibula. They, too, are surrounded by fascial extensions and are overlain

by large muscle bellies. The return blood supply of the deep flexors of the forearm is thru the deep median vein which becomes almost superficial in the antecubital space. The return supply of the flexors of the foot is thru the posterior tibial vein which passes thru a window in the popliteal fascia.

Therefore, there is no valid reason why a disorder so prevalent in the forearm, should be so rare in the leg. Perhaps the lack of specialization of the leg muscles masks the result of muscle damage. It is possible that some of the delayed functional results of fractures of the leg are due, in part, to unrecognized fibrosis of the calf group.

If we analyze critically the deformity of the forearm, it is seen that the deep flexors are the most abused. All true Volkmann's contractures present a flexion contracture of the terminal phalanges which is modified in part, by acute flexion of the wrist.² The long flexor of the thumb likewise is involved. In an analysis of all the true cases appearing in the English literature since 1916 (in which sufficient data was given from which conclusions can be drawn) it is seen that these two muscles suffer the greatest damage. This is more than a pure accident. The fact that these two muscles lie nearest the interosseous membrane and are more completely bound down than are the superficial group, leads one to believe that unrelieved congestion plays a great part in the resultant deformity. It is perfectly good mechanics to postulate distension of a deep muscle group with resistant increasing pressure thereupon from the muscles which directly overlie them. In the leg, the posterior tibial and the long flexors of the toes are similarly situated, hemorrhage into them, if no decompression of the superficial muscles occurs, should be more deleterious than that in a muscle not so tightly circumscribed.

From this, then we could reasonably expect flexion contracture of the posterior tibial muscle and a calcaneo varus deformity of the foot with marked flexion of the toes. The case which follows presents these.

Case Report Mr F H. Aged 44, not now employed but who was formerly a waiter, a clerk and a salesman, presented himself for relief of pain under the long arch of the right foot. At the age of two or three years, the patient had an open osteotomy for bilateral bowleg. (Skin scars are still present and are shown in the accompanying sketch.) The left leg healed perfectly with a curve of the condition. As near as the patient can remember (the hospital reports of 1889-90 are not available) the pain in the right leg caused the plaster cast to be removed. A long series of operative corrections followed the last treatment of

which was in 1911, when an attempt was made to correct the varus deformity by manipulation. The patient wore the cast only a short time and abandoned all attempts at cure.

The patient now presents himself for relief of long arch pain worse after exertion and totally bettered by rest. This part of the picture is probably due to foot strain.

Physical examination of the right leg and thigh reveals a bottle shaped leg, i.e., there is a very

FIGURE 1

Sketch to show bottle-like deformity of leg and calcaro-cavus deformity of right foot.

definite change at the junction of the middle and upper third of the leg. Above this point, the contour is, barring atrophy, approximately normal; below this point the leg resembles an inverted bottle neck. There is a calcaneo-varus foot with moderate adduction of the forefoot. The toes are held in marked flexion. There is a very slight amount of passive motion possible in the ankle joint. The only muscles having active motion on the posterior surface are the two approximately normal bellies of the gastrocnemius above the line of demarcation mentioned before. There is no active inversion of the foot, no active eversion and a very small amount of flexion and extension of the toes due to the short flexors and extensors. There is no anesthesia, no abnormal nerve signs.

The right femur is one and a half inches longer than the left with one and three-quarters inch shortening of the right leg.

FIGURE 2

Sketches to show relations of the deep muscle groups to the interosseous membrane and overlying bellies and tendons. (Grays Anatomy, pages 473 and 530, Lea and Febiger, 1913.)

SUMMARY

A case of Volkmann's contracture of the leg is presented in an attempt to stimulate interest in this entity as applied to the walking extremity.

It is possible that unrecognized Volkmann's contracture of the leg, following fracture of the leg bones, constitutes an important factor in delayed functional cure.

ORAL SURGERY OF INTEREST TO THE MEDICAL AND DENTAL PRACTITIONER¹

By THEODOR BLUM, D.D.S., NEW YORK, N. Y.

THE opportunity to appear before a combined medical and dental audience is always welcome, because in spite of the numerous papers and lectures on the subject of the necessity of cooperation between the two professions, the required understanding and the necessary respect have not as yet developed to any appreciable degree. The fact that the medical student does not receive instruction pertaining to the jaws, teeth and surrounding structures, and that the medical education of the dental student is not adequate at present must be largely blamed for the existing misunderstanding. With the intention and hope that it may be of interest and benefit to both, physicians and dentists, an attempt will be made to enumerate a few important conditions, which both professions should know about and are often called upon to consult each other.

The dental examination consists of much more than a casual glimpse at the teeth or gums. A complete x-ray examination consisting of at least fourteen intraoral and two extraoral films, a pulp-test of all teeth and often transillumination are absolutely necessary and should be insisted upon before anything but emergencies are attended to. Only then is the dentist or oral surgeon (who is at present most often the oral consultant or diagnostician) placed in a position to intelligently discuss a patient's condition, for instance, dental focal infection. In this connection, I wish to say that in such a case the consultation with the physician is of great importance, he will tell us when devitalized teeth, negative from the dental standpoint, must be sacrificed. But aside from this I believe that the dentist—if for no other reason than to safeguard himself—should communicate with the medical practitioner, before commencing the treatment of a new patient. Many unpleasant experiences in cases of diabetes, heart disease etc., will thus be avoided. Of course radical treatment is not always indicated and quite often useful and important teeth can be saved for many years in spite of a pathological condition of the apex by root amputation.

Today most every disease of the mucous membrane of the mouth is called Vincent's Angina, Trench Mouth and sometimes by a better term, namely, Vincent's infection by physicians and dentists. But to the doctor's great surprise, smears taken from different parts and depths often do not show the fusiform bacillus and the spirochete. It is more appropriate to speak of ulcerative gingivitis and stomatitis particularly because no matter what organisms are found, the main treatment consists of daily light prophylaxis

and the application of whatever drug one finds most efficacious in individual cases. Surgical interference during the acute stage is contraindicated. To my mind, osteomyelitis as a complication of ulcerative gingivitis is due to surgical interference as above mentioned, or to unduly vigorous instrumentation, which amounts to as much. While speaking of osteomyelitis of the jaws, I wish to recommend extreme patience to both practitioners, while dealing with this condition. Watchful waiting, draining pus collections and removal of sequestra if they are fully separated only, make up its successful treatment. All patients suffering with this and many other diseases require the care of a physician or at least his cooperation with the dentist in charge for the most efficient combatting of the condition and an uneventful and rapid recovery.

Malposed teeth if completely unerupted do not constitute a possible focus of infection. However, they and their subdivisions, like impactions, are quite likely to cause facial pains, absorptions of adjoining teeth and the impacted one with consequent involvement of the pulp, and if partly erupted, acute infections with fatal results sometimes, unless treated conservatively. It is for these reasons that I have advocated for many years now, the removal of all malposed teeth (not malposed in the sense of the orthodontist) whenever detected with the exception of those, which in cooperation with the orthodontist can be exposed and slowly forced into their normal position.

There are two types of dental cysts, to which I want to call your attention. The radicular cyst originates from a devitalized tooth and develops in its apical region, while the follicular one forms around the crown of a malposed tooth, which crown projects into the cyst cavity. The malposed tooth is removed in most instances at the time of the operation. In a number of cases the tooth or teeth involved in the radicular cyst area can be saved by root canal therapy, followed by root amputation. Granulomas at the apices, which may or may not develop into cysts—depending on the presence or absence of epithelial cells—should always be removed in chronic cases at the time of the extraction if removal of the tooth is advisable. Dry sockets unfortunately occurring only too frequently after the removal of teeth, must never be curetted; all debris is gently removed, the socket carefully dried with cotton swabs and dressed with iodoform gauze saturated with dentalone, which dressing is changed every day or two. While on this subject it may not be amiss to say a few words about extracting during an acute stage, namely, when a purulent periostitis

¹ Read before the Second Combined Medical and Dental Meeting of the Westchester Dental Society, December 15, 1931.

coexists. There is no objection to the removal of the tooth, although there is as a rule no indication for it. However, the main treatment consists of the evacuation of the pus by a liberal incision. Any further surgical interference should be deferred to the chronic stage.

The antrum naturally belongs to the field of the rhinologist. Only those diseases of this sinus caused by infected teeth or the bone in this region or roots pushed into the sinus, etc., are better cared for by the oral surgeon provided the other sinuses on the same side are not involved. No treatment of the antrum should be undertaken without *x*-ray examination of all sinuses as well as *x*-rays and pulp tests of both maxillae and teeth. Postoperative irrigation by the oral route can easily be accomplished by a method described elsewhere.²¹

The examination of the salivary glands is very frequently omitted or neglected and therefore stones in the glands and ducts only diagnosed when they give symptoms. In this connection I must say that I never had to resort to the removal of the gland for the treatment of sialolithiasis and only once removed a stone extraorally. Please remember also that in spite of the presence of a stone the *x*-ray examination may be negative.

Trifacial neuralgia must not be forgotten, when dealing with diseases of our field. The etiology is still obscure and removal of sound teeth entirely contraindicated. The treatment of choice is the operation perfected by Frazier, which is accompanied by a mortality of less than one per cent. The difficulty lies only in the diagnosis of doubtful cases. Facial pains, so-called, are quite a different complaint. They may be temporarily relieved by various medical and surgical interferences, but return quite regularly unless the cause is found and remedied.

The treatment of fractures of the jaws is the only borderline condition which practically always is turned over to the dental or oral surgeon. But here also, especially in severe accidents, the cooperation with the physician or surgeon is more than welcome.

Cancer being so prevalent, this paper cannot be closed without giving some space to the subject of tumors. The term epulis so frequently used should be confined to those proliferative masses showing inflammation appearing at the gingiva.

A giant cell tumor must not be confused with a giant cell sarcoma, which is a highly malignant neoplasm rarely found in the mouth. The giant cell tumor and osteitis fibrosa are not neoplasms, but central proliferative masses representing probably different stages of the same process.

Any abnormality about the mouth and face should be looked upon with suspicion, every specimen removed examined histopathologically and slide and specimen preserved and indexed. Small masses, which do not require extensive opera-

tions, are best completely removed first and then a cross-section examined. Because you find fluctuation the condition must not necessarily be a cyst or an abscess. To sum up this question, I would say that we can serve our patients best by diligently and carefully correlating our clinical observation, *x*-ray findings, and histopathological evidence. Neoplasms requiring intimate combined radium, *x*-ray and surgical treatment are best cared for by men in both specialties or in institutions specializing in this field.

It is impossible, of course, to mention even all the important conditions encountered in this region, less so to deal with them in detail. For those interested, a bibliography of previous articles is appended.

Why is this close cooperation of the two professions still lacking? My answer is that it is not so much the fault of the physician and dentist, but rather of the schools, the entire educational system, which makes the American student a hunter of diplomas, which waste his time and money. Any intelligent human being can receive all the preliminary education necessary for the entrance into a medical or dental school up to and inclusive of his or her eighteenth year. Then there will be plenty of time for the maximum of professional education, namely, four years of undergraduate study, two years of hospital internship and if so desired, another two years in the study of a special field: a saving of four years at least. Why should not a medical or dental student practically live in the hospital like a nurse in training does, who after graduation leaves the school by far better equipped for her profession than the medical or dental student? All this can be accomplished by elimination of bad politics and its accompanying waste of money, politics not only of state and city governments, but in all schools, low and high and professional and in hospitals.

THE RESPONSIBILITY OF THE PRACTITIONER IN MENOPAUSAL BLEEDING*

By JAMES E. KING, M.D., BUFFALO, N. Y.

THE menopause is characterized by profound changes that involve the genital organs, the general physical condition of the woman, and the endocrine glandular system itself. Beyond the fact that the endocrine glands are primarily responsible for these changes, we know little of the delicate glandular readjustments that take place at this time. There are many false notions concerning the menopause which have been and still are tenaciously held by the laity, and which are accountable for many unnecessary deaths. Unfortunately, the profession, too, is in some measure responsible for fostering these false views.

For approximately thirty-five years menstruation recurs normally every twenty-eight days, interrupted only by pregnancy and lactation. It is known that menstruation is not the result of the ovary acting independently but that it depends upon a complex interaction of several glandular structures. It is obvious then that with the cessation of reproductive life the readjustment of those endocrine glands upon which reproduction depends, will be followed by certain phenomena. If the readjustment proceeds smoothly the functional and physical changes that take place will cause no inconvenience or discomfort. On the other hand, if, during the readjustment, a delicate glandular balance is not maintained, pronounced disturbances of various kinds will be the result. It is very difficult to draw hard and fast lines between a normal and abnormal

menopause and in a given individual this question can not be settled always upon any single manifestation but rather the entire picture presented must be considered.

It is not within the scope of this paper to theorize upon the glandular changes that take place at the menopause nor to discuss in general the clinical manifestations. We are only concerned with the question as to what constitutes a normal or an abnormal type of flow at this time. There are two common normal types observed. The first is the gradual loss of menstrual function, indicated by decreased flow recurring at prolonged irregular intervals. The second is the sudden, abrupt termination. The gradual withdrawal of menstruation is by far the more common and within normal limits great variation is seen in the interval between the recurring flow and the length of time over which such irregularity may persist. As to what constitutes abnormal flow can be stated dogmatically and safe principles can be laid down to guide one in judging between the normal and an abnormal bleeding. There are five of these principles. The first is that any increase in the amount of flow is abnormal. The second, that any shortening of the intermenstrual period is abnormal. The third, that any prolongation of the flow is abnormal. The fourth, that any intermenstrual flow is abnormal. And fifth and finally, re-appearance of bleeding a year or more following complete cessation is abnormal. If these facts can be burned into the consciousness of every woman and every member of the profession, a long, long step will have been taken toward the

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 2, 1931.

prevention of many tragic and untimely deaths. It is frankly admitted that exceptionally any of these abnormal bleeding types may be seen during a normal menopause, but no physician has any moral right to assume that such exceptions are normal until he has definitely proven it to be so. It is true that there are a number of benign conditions that cause abnormal flow and which, in due course of time, disappear. But here again the same rule holds true, no physician has any right to assume that the source of such bleeding is benign until it has been so proven. It is abnormal bleeding resulting from benign conditions that is responsible for the popular view that normal menopause is often associated with increased and irregular flow.

In order to approach menopausal bleeding intelligently it is essential that one be familiar with all those conditions which may cause such bleeding, and have clearly in mind the procedures necessary to determine their diagnosis. It is proper, first, to divide such conditions into those that involve the cervix and those that involve the body of the uterus and these again into lesions that are benign and those that are malignant. Of the conditions involving the cervix the benign lesions may be enumerated as cervical mucous and fibroid polyps and cervical erosions, especially those of the papillary type. All of these lesions are simply and easily diagnosed by digital examination and inspection. Their clinical manifestations are untrustworthy and not to be relied upon in determining a diagnosis. The symptoms, therefore, are of little importance in this discussion.

The malignant lesions of the cervix are obviously the most important. There are two kinds. The first is the squamous cell carcinoma of the portio of the cervix, and the second, the adeno-carcinoma of the cervical canal. The squamous cell carcinoma is ten times more frequent than the adeno-carcinoma of the canal. Indeed, it is many times more frequent than all other forms of malignant disease that involve the uterus. It is of practical importance, also, to bear in mind that there are two more or less distinct types of squamous cell carcinoma. Both types take their origin from the squamous epithelium covering the surface of the cervix but in the one the malignant cells develop *into* the cervical tissue, and in the other the malignant cells tend to *pile up* on the surface. The first is quite appropriately designated as the infiltrating type and the second the proliferating type. This distinction has a practical bearing both on the clinical course and in the diagnosis. It is not pertinent here to analyze the character of the bleeding that may result from

early squamous cell carcinoma. The all essential fact is that such malignant growths do cause abnormal bleeding which demands prompt investigation by the physician. The fact that the squamous cell types develop on the surface of the cervix makes it possible to

Patient Aged 53
Polypoid Endometrial Hyperplasia.

discover such lesions by examination even in their early stages. There may be difficulty in differentiating between the early proliferating carcinoma and a papillary erosion. Any uncertainty, however, can be settled by a tissue diagnosis. The question as to whether excision of tissue in such cases favors lymphatic extension is important, but until conclusive evidence has been produced to prove such a contention biopsy is eminently justified.

The adeno-carcinoma that begins and develops in the cervical canal presents a different diagnostic problem. Being sheltered within the canal it is less subject to those injuries that may produce early bleeding in the more exposed type. Early bleeding, therefore, in adeno-carcinoma is not as common. Examination, too, will often disclose very little. Possibly by palpation the cervix may be found to be harder and larger than normal. Inspection, also, may add little. There is, however, one valuable test that should not be forgotten when this type of malignancy is suspected. If a sound be carefully inserted into the cervical canal in the presence of carcinoma bleeding will result. In the normal canal gentle manipulation should not produce bleeding.

Both the benign and malignant conditions of

the cervix which have been mentioned are also usually associated with discharge. Naturally, complaint of a discharge during the menopausal years should receive just as prompt consideration by both patient and physician as bleeding.

Bleeding from the body of the uterus occurring during the menopause can also be classified, as in the case of the cervix, as resulting from benign and malignant lesions. The benign lesions are: hypertrophic endometritis, fibroids, fibroid polyps, mucous polyps, and rarely, atrophic endometritis. Of the malignant lesions the adeno-carcinoma is the chief, the sarcomas being rare.

In the group of benign lesions there are at times clinical and physical signs that make it possible to establish a diagnosis with reasonable certainty. As a rule, however, clinical evidence is very untrustworthy and to depend upon it is courting danger and inviting disaster. For this reason, it is much safer, especially for those of limited experience, to ignore more or less the clinical manifestations and to rely for diagnosis upon the evidence to be obtained by a proper and comprehensive examination. To do this it is necessary to have in mind certain characteristic features of the pathology that may cause bleeding. Such knowledge at once suggests the procedures necessary both for diagnosis and treatment.

Hypertrophic endometritis is a common condition about which there is still much to be learned. It may occur at any age during the reproductive life of women. It is more common, however, just preceding and during the

Patient Aged 55

Polypoid hyperplasia (right) adeno-carcinoma (left)

menopause. It is characterized by a definite thickening of the endometrium with an increase in the number and tortuosity of the glands. There are varying degrees of this condition. From a moderate thickening one may see all stages up to an enormous hypertrophy, with deep folds of membrane and the formation of polyp-like processes. This form is called polypoid endometritis. When the ducts of the glands become dilated the term cystic endometritis is used. The curet here is the diagnostic agent and it will bring away, in well marked cases, a large quantity of velvety membrane which to the experienced eye often establishes the diagnosis. These cases especially at the menopause have one characteristic that should be remembered: there is a tendency to recur following removal. A few months after curettage the bleeding reappears. This may be repeated several times until finally the pathologist reports the scrapings as malignant. This tendency to final carcinomatous change places recurring hypertrophic endometritis in the class of so-called pre-malignant lesions.

For reasons already stated no attempt will be made to analyze the type of bleeding resulting from endometritis. It is sufficient to know that bleeding does occur. It is the business of the physician to establish the diagnosis by other means than by clinical evidence. Bleeding fibroids at the menopause should not be taken for granted. The presence of such a

Patient Aged 51

Extreme endometrial hyperplasia: curetted twice within six months

tumor naturally suggests it as the lesion entirely responsible for the hemorrhage. A fibroid which is growing and assumes a new activity at a time when regressive changes should be taking place, ought always to be regarded with suspicion. Degenerative changes of various kinds are common in these tumors during the menopause. It is for this reason that a blind reliance upon x -ray treatments for bleeding fibroids at the menopause is fraught with danger. A number of instances have come under the writer's observation in which, after a series of x -ray treatments and loss of much valuable time, the patients were found to have an adeno-carcinoma complicating the fibroid.

The mucous and fibroid polyps of the uterine cavity require no extended discussion. With the few exceptions in which painful expulsive contractions occur there are no clinical evidences that can be relied upon. Atrophic endometritis is comparatively rare. It does not commonly give rise to bleeding but more

body is seen more commonly in women who have not borne children. It usually appears at varying periods following the menopause. This fact makes bleeding that occurs one or more years after the menopause of great significance. It is seen, however, with sufficient frequency during the time when the menopause is being established and in women who have borne children to make it necessary for every

Small fibroid causing serious menopausal bleeding: dark area indicates site of bleeding.

Infiltrating squamous carcinoma of the cervix.

frequently causes a bloodstained discharge which is not distinguishable from that of the early carcinoma of the body.

Adeno-carcinoma is obviously the most important lesion of the endometrium that produces bleeding. In a practical discussion it is not necessary to indicate the several forms which may be found but to point out certain practical clinical features. Carcinoma of the

physician to keep the possibility of its occurrence constantly in mind. As a general principle, however, the longer after the menopause that bleeding occurs the more probable it is that a carcinoma is responsible for it. The lesion, being sheltered within the uterine cavity, is not subjected to the traumas that the malignant conditions of the cervix are. A pinkish, serous discharge is often the first indication the woman has. Nor does the extent of the lesion always indicate the amount or type of bleeding produced. The body of the uterus is enlarged as the disease progresses and pain is never an early indication. A sound in the uterus is often a valuable aid in making a diagnosis.

In this brief reference to the various conditions of the cervix and uterine body that may cause bleeding during the menopause there are a few facts applicable to both that stand out prominently. There are no symptoms which alone can be relied upon to diagnose any of these conditions. Dependence must be placed upon a careful and proper examination. Diagnosis is a comparatively simple procedure in case of cervical lesions. Uncertainty is most liable to arise in differentiation between certain cervical erosions and malignant disease. In the more advanced cervical carcinomas there is, of course, sufficient evidence to dispel any doubt. In the less advanced and doubtful cases any question should be promptly settled by biopsy. Not so long ago it was customary to "watch" the condition and when finally the physician awoke to the fact that he was dealing with a carcinoma the patient perhaps had passed beyond the stage when any procedure offered hope of cure. Today such dallying is rarely seen. Women, too, have become more cooperative and a frank statement by the physician as to his doubt and the reason for it, usually results in whole-hearted cooperation on the part of the patient. Examinations are sometimes delayed because the patient is flowing. In former years it was considered very indelicate to attempt examination with bleeding present. This, too, has

changed. A little tact puts the woman at ease and the cause of bleeding can earlier be ascertained, the remedy more promptly applied, and blood saved to the patient.

In the diagnosis of conditions effecting the body of the uterus the pelvic examination is far less conclusive than in the case of cervical

*Patient Aged 52
Large fibroid polyp which caused free bleeding*

Early squamous cell carcinoma

lesions. Here there is only one safe and certain means of diagnosis, exploration and curettage. No physician should hesitate to admit his inability to diagnose a condition which he can neither feel nor see. The possibility of a carcinoma of the endometrium complicating a fibroid uterus should cause one to hesitate in ascribing the bleeding to the fibroid in every case. Certainly at the menopause there should be no delay in removing the fibroid unless curettage has demonstrated that there is no malignancy present. Curettage, in the cases under discussion, should be regarded as an essential diagnostic procedure. The competent laboratories now maintained by county and state health departments offer every facility for the diagnosis of such tissue. It is important to remember that the curettage, to be of value, must be thorough, all the scrapings carefully collected, and the entire material submitted to the laboratory.

The treatment of cervical and intrauterine conditions causing bleeding at the menopause is too large a question for discussion at this time. Many cases are to be dealt with surgically with the use of x-ray and radium in

Patient Aged 49
Proliferating squamous cell carcinoma.

selected cases. While many practitioners may not have the facilities for treating all cases, every physician should be and is capable of assuming the responsibility for a correct diagnosis. As a result of educational campaigns women are coming to appreciate as never before the need for prompt and thorough examinations and to expect from the physician a positive diagnosis. The physician who without examination casually dismisses these cases as due to the "menopause" can not have, nor does he deserve to have, the confidence of the community which he serves.

The entire subject may be summarized in a practical way by four precepts:

1. In abnormal bleeding at or near the menopause the physician should not be content with anything short of a positive diagnosis as to its cause.
2. Biopsy of cervical tissue or examination of material removed by the curet afford in certain cases a sure means of diagnosis.
3. X-ray treatment should never be employed until carcinoma has been excluded
4. Physicians and nurses should constantly seek to dispel the false views held by many women concerning menopausal bleeding.

THE PROPEPTAN THERAPY OF LUTHLEN-URBACH IN THE TREATMENT OF ALLERGIC SKIN DISEASES CAUSED BY FOOD

By JAMES M. MARKIN, M.D., ROCHESTER, N. Y.

From the University Clinic for Syphilis and Dermatology of Vienna, Director, Prof. Dr. W. Kerl.

FOOD allergy is sometimes known to be the cause of a variety of skin diseases—urticaria, prurigo, lichen urticatus, strophulus infantum, eczema and angioneurotic edema; gastro-intestinal symptoms; asthma; migraine; convulsions, etc. These conditions are very often resistant to the usual methods of treatment, especially if the real cause is unknown.

Various methods of therapy have been used. Autohemotherapy and serotherapy have been employed as desensitizing measures. Laroche¹ Richet and Saint Girons did not recommend it. Duke² states regarding his experience with non-specific protein therapy (in the form of

colon bacilli) given intravenously or subcutaneously, that "good results if obtained are rarely permanent." Intracutaneous injections of the specific protein have been at times successful.

The treatment of allergic food conditions by the oral route has consisted of some of the following methods: 1) *True oral desensitization*, by administering the offending food in graduated doses. 2) The indigestion of small quantities of food which are to be taken one hour later at the regular meal have been found sometimes to result in desensitization.

The first men to employ unspecific peptones i.e. the common commercial peptones were

Pagniez, and Pasteur Vallery-Radot³ who reported a moderate percentage of relief Auld⁴, an Englishman, reported better success with the use of two kinds of peptones, animal and vegetable Luthlen⁵ was the first to work with the special specific peptones i.e. peptones derived from protein to which the patient is sensitive After Luthlen's death Urbach⁶ developed this method further and made it practical for therapy

Experience with this method in the Kerl clinic was so convincing of the practicability and high percentage of relief to be obtained, that I deem it justified to give the methods employed in detection and desensitization in detail, and to indicate the results obtained therewith The more so as the more widespread application will show the ultimate value of the method

METHODS OF DETERMINATION OF CAUSE OF ALLERGIC CONDITION

If it is believed that a child or adult is sensitive to a food, as determined by the symptoms and a careful family history, one may begin with a diet poor in protein If possible the patient is taken into a hospital and the same diet to which he is accustomed is given for two days, to determine whether extrinsic or intrinsic allergy is present If, after two days the same subjective and objective symptoms are found, a diet, as suggested by Urbach, is given for two days as follows

8 a m	Tea (without milk) and sugar Bread
12 noon	Soup—made of water, flour, potatoes and carrots Stewed apples
4 p m	As at 8 a m
8 p m	As at noon

In many cases a good effect regarding objective and subjective symptoms will be noticed within 24 to 48 hours If this occurs a new protein food is added every day and the day on which the symptoms reappear it is removed If the symptoms disappear the food is given a second time to make certain that that food is the cause of the symptoms

If the patient has had no effect with this diet, we cannot say that protein is not the cause of the condition, for especially in children also the protein of wheat, potatoe and carrots can be the causative factor

For this reason and because it is not always possible to give so limited a diet, Urbach suggests the use of his Propetan test The principle of this test is to feed the patient only those protein foods for which are prepared the specific peptones called Propeptan* as termed by Luthlen⁵ and Urbach⁶ These peptones

are administered exactly $\frac{3}{4}$ hour before the meal as illustrated below

Hour	Propeptan	Hour	Foods
7 15 a m	Egg, milk, wheat	8 00 a m	Egg, toast, butter, coffee, milk, sugar
11 15 a m	Chicken, potatoes, carrots, strawberries, milk, wheat	12 00 noon	Chicken soup, bread butter, chicken potatoes, carrots strawberries, cream
5 15 p m	Fresh water fish, peas, potatoes, wheat milk, banana	6 00 p m	Bass, potatoes tomatoes peas, bread, butter, banana

The Propetans are prepared in tablets of $1\frac{1}{2}$ grains each according to the method of Luthlen and up to date there are 25 types These were furnished by the Chemosan Union, Vienna III, * * and were derived from the following foods Veal, beef, lamb, pork, chicken, salt-water fish, fresh-water fish, crabs, egg, milk, cheese, rye, wheat, carrots, potatoes, spinach, tomatoes, beans, peas, lentils, rice, sauerkraut, cocoa, bananas, strawberries Other Propeptans may be prepared, as for example horse meat Propeptan, which was administered in a case to be described a little later

The advantage of this method is that the patient is most apt to get immediate relief of symptoms and at the same time enjoys a diet which is both agreeable and of a sufficient caloric value

If a person loses within three or four days a great part of his subjective and objective symptoms then one may feel that he is following the right course At the time when the patient loses all symptoms one type of Propeptan is removed each day If following the removal of milk or another Propeptan a fresh outbreak of symptoms occurs then the Propeptan is removed a second time for accuracy A recurrence of symptoms demonstrates a sensitiveness to that food

Not infrequently people are sensitized to 2, 3, or more foods and for this reason it is necessary to test systematically for sensitiveness to all of the accustomed foods of the patient

The "Elimination Diets" as suggested by Rowe⁷ who has done a good deal of work in America on Allergy, will be found also very useful These diets, five in number, contain

* *Method of Preparation* on The food substance is freed as far as possible from fat hulls etc and reduced mechanically to its smallest elements Next the resulting mass is allowed to digest in a watery solution mixed with the required quantity of effective pepsin until no native albumen can be found Then the pepsin is destroyed by boiling the liquid is freed from the insoluble substances by filtering it is next dialysed and the pepton contained in the solution is precipitated The final product a yellowish to dark brown powder is pressed into tablets

** American Representatives—American Biochemical Laboratories Ltd 235 Fourth Ave New York City

foods, which cause least frequently allergic disturbances. After finding the diet which relieves the symptoms, other foods are gradually added, every food causing symptoms being excluded.

It may be difficult at times to determine the agent responsible for the reaction. One should then think of the unusual foods. The following two cases which I have seen, serve as illustrations. In a recent case of a child of poor parents who was sensitive against sausage, the commonly used ingredients of sausage were given to the patient but without resulting symptoms. Finally, after trying horsemeat, this was found to be the disturbing element. With the administration of the specific Propeptan, the patient remained free of symptoms. In a second case where a man was sensitive to sausage, it was determined that pepper caused the lichen urticatus and not protein.

In chronic types of urticaria where the common protein foods were found to be tolerated one must think of the vegetable proteins, especially those belonging to the leguminous group as lentils, beans and peas. Occasionally, one also finds the cause in fruits. I have seen a case of hypersensitiveness against lemon, one against orange, another against apple. Butter may be a causative factor, either in connection with milk hypersensitiveness or alone. For the butter, milk Propeptan is used.

TREATMENT

If the cause of the allergy is determined the treatment is as follows:

First: *Avoidance of Cause.* Non-vital foods such as bananas, crabs, etc., may be omitted from the diet.

Second: *True Oral Desensitization*, where the foods are essential or cannot be conveniently avoided; by minute dosage of offending food in increasing amounts until tolerance is developed (this method is, however, not without danger and requires experience to avoid serious reactions.)

Third: *The Propeptan Method.* The offending food or foods are included in the patient's diet but are preceded $\frac{3}{4}$ hour by the corresponding specific Propeptans in 1-2 tablets ($1\frac{1}{2}$ -3 grs.) dosage per protein. At least four hours should elapse from the previous meal. Occasionally it may be necessary to administer more than two tablets, i.e. up to three or four. A period of 2 to 3 weeks of daily administration usually suffices to produce desensitization.

RESULTS

In order to demonstrate that the Propeptan method is not alone important for the treat-

ment of allergic skin reactions but also for other manifestations of food allergy, I describe first two cases presenting gastro-intestinal disturbances.

S. M., Female, age 13 months (my own child). About 8 hours following ingestion of egg, vomiting, diarrhea and colic occurred. An urticarial eruption of a somewhat longer duration appeared later. Following ingestion of 2 egg Propeptan tablets (grs. 3), 45 minutes before her meal containing eggs, no symptoms were noticeable. As the child was an infant and was sensitive only to egg, no attempt as yet has been made to desensitize her.

F. M., Man, age 33 years. Following a Billroth resection of the stomach for a duodenal ulcer, the patient complained of severe nausea, tachycardia and sweating immediately following his meals over a duration of four years. He stated when he first appeared at the hospital that he was only able to drink tea at that time. Lost 13 Kilos in four years. X-ray investigation showed that the stomach had good functional anastomosis. Gastric juice decreased, HCl 11, total acidity 19. By the Propeptan diet test, it was found that the patient was sensitive to egg, milk and mushrooms. After drinking half a pint of milk or eating a quarter of an egg, he developed severe nausea, tachycardia of 120 and a general outbreak of sweat. After taking 1 Propeptan tablet ($1\frac{1}{2}$ gr.) of egg in the usual manner, the symptoms appeared but somewhat delayed. After administering 2 egg Propeptans the symptoms were more mild and appeared after two hours. After 4 Propeptan tablets the patient remained free of symptoms. In order to see whether the effect of the peptones were specific or not, the patient was given, without his knowledge of the change, 4 chicken Propeptan tablets in place of the egg type. After 7 minutes he developed a severe attack of tachycardia. The treatment consisted in the daily feeding of milk and egg with previous administration of Propeptans. In the first week he received 4 Propeptan tablets of each, in the second week 2, and in the third and fourth 1. After 2 weeks his weight increased 2 Kilograms. After 4 weeks he was desensitized to egg and milk.

From a dermatological aspect, Lichen Urticatus and Strophulus Infantum are most often the cutaneous expressions of food sensitization. Urbach⁸ states that 90% of the cases of Lichen Urticatus and Strophulus Infantum are caused by food. The most frequent offending foods are eggs, milk, pork and wheat.

E. M. Female, 10 months. Had severe Strophulus Infantum. After albumin free diet, symptoms were little improved. Child was

given Propeptan diet for 3 days, at the end of which time she was quite free of symptoms. Upon removal of wheat Propeptan a fresh attack occurred on the following day. Wheat Propeptan was again administered with the same good results as formerly. Six days later a cereal (wheat) was fed to the child which resulted in a fresh attack. The removal of the other Propeptans resulted in no symptoms. After two weeks in which the child took twice daily wheat rolls with Propeptans she was permanently desensitized.

S M Daughter of an American physician, age 2½ years. Lichen Urticatus. Mother gave history of being allergic to strawberries. Child had no skin eruption until she came to Vienna. The child was placed on a diet containing tea with sugar, bread, soup made of water, flour, potatoes and carrots, and stewed apples. Only slight improvement occurred. She was next given Rowe's Elimination Diet No 1 and the symptoms immediately disappeared. Other foods were added to the diet. Following the ingestion of wheat and rye bread the symptoms reappeared and upon eliminating the bread the urticaria cleared up. The child was fully desensitized after 14 days by the daily administration of 2 wheat and 2 rye Propeptan tablets given ¾ hour before the meal containing wheat and rye bread.

I have seen a girl of 15 years with characteristic lesions of Prurigo (Hebra) with much enlarged hard lymph glands. Duration 9 years. Milk and beef were found to be the causative factors. The corresponding Propeptan treatment was given over a period of 3 weeks. The skin lesions and lymph glands disappeared entirely and now the patient is able to drink milk and eat beef without peptonates and with impunity.

Sometimes nutritive allergy appears in very unusual Dermatological manifestations as seen in the two following cases. Thus, first, was seen a case similar to dermatitis herpetiformis (Dühring) in an elder woman with residual bullae and with extreme itching. The duration of her condition was ten years. She was found sensitive to egg. Her lesions cleared

up following the administration of Propeptan for 4 weeks.

The other case*¹ was a woman who suffered for three years of a so called urticaria cum pigmentatione beginning with urticaria and vesicles. Beef and veal were found to be the offending foods. The patient was cured by the specific Propeptan therapy.

SUMMARY

In cases in which the history or the symptoms of a patient speak for nutritive allergy, one may use the so called "nutrition experiment" ("Ernährungsexperiment") of Urbach, "Elimination Diets" of Rowe, or the Propeptan method of Urbach to determine the offending food or foods.

For desensitization the Propeptan therapy is recommended. Three quarters of an hour before the meal containing the offending foods the corresponding Propeptans are administered daily. Desensitization generally occurs in about two weeks.

Good results were seen in nutritive allergic conditions of lichen urticatus, urticaria, prurigo, in a peculiar type of chronic eczemas*² as well as in cases of intestinal allergy, and other allergic conditions caused by food.

RECENT AGE TRENDS IN POLIOMYELITIS

By MILDRED WEEKS WELLS, MD, NEW YORK, N Y

IN recent years a tendency toward an increase in the incidence of poliomyelitis in the higher age groups has been noted. Undoubtedly this is directly contrary to what one would expect, considering the greatly increased intercommunica-

tion of late years and a presumably increased dissemination of the virus. This subject has seemed of sufficient importance to justify a preliminary publication of some of the data which have been collected in the course of an epidemiological study

of poliomyelitis made under the auspices of the International Committee for the Study of Infantile Paralysis.*

Forsbeck and Luther (*N. E. J. Med.*, 203:1115, 1930) called attention to such a trend in age distribution in Massachusetts. Up to about 1918, there was apparently little or no change in the age distribution. Since then, the relative number of cases in the 0-4 year group has markedly decreased, while there has been a compensatory increase in the relative number of cases in the age groups 5-9 and 10-14. The percentage of cases occurring in the age group 15-19 and in adult life has remained fairly constant. Figures taken from a table prepared by these authors, together with figures obtained through the courtesy of Dr. Gaylord W. Anderson, show this trend. (Table I.)

TABLE I

PERCENT OF DISTRIBUTION OF CASES OF POLIOMYELITIS IN MASSACHUSETTS BY AGE GROUPS

Year	Total No. of Cases	Per Cent of the Cases in Age Groups	0-4 Yrs.	5-9 Yrs.	10-14 Yrs.	15-19 Yrs.	20+ Yrs.
1916.....	1,927	69.7	19.8	5.9*	*	4.6	
1920.	696	53.2	25.3	10.3	5.2	6.0	
1924.....	277	47.0	24.2	14.6	5.6	8.6	
1927.....	1,189	45.9	30.9	11.4	6.0	5.8	
1930.....	503	38.1	38.9	12.6	5.2	5.2	
1931.....	1,428	27.6	40.6	16.2	8.0	7.6	

* For 10-19 yrs. in 1916 grouping.

Knowlton reports a similar trend in Connecticut (*Month. Health. Bull., State of Connecticut*, 46:3, 1932). The most striking example is seen however in the figures of the age incidence in the three major epidemics from which New York City has suffered. Our attention was called to this by Dr. Jungeblut. Table II gives the age grouping for New York City, 1907, 1916, and 1931. The figures for 1907 are unfortunately not given by standard age groups, so that to facilitate comparison the cases for the 1916 epidemic have been given by both age groupings.

TABLE II

PERCENT OF DISTRIBUTION OF POLIOMYELITIS CASES BY AGE GROUPS IN NEW YORK CITY IN THE EPIDEMICS OF 1907, 1916, AND 1931

Age Group (Old Style)	1907 ¹ Cases	1916 ¹ Cases	Age Group (Standard)	1916 ¹ Cases	1931 ² Cases
	729	9,131		9,131	3,898
0-1	8.5	11.1			
1-5	82.0	74.7			
6-10	6.4	10.5	0-4	79.2	53.3
11-15	1.9	1.9	5-9	16.2	30.8
16-207	.6	10-14	2.4	10.3
Adults4	1.2	15-19	.8	2.9
			20+	1.3	2.7

¹ The age incidence for the 1907 and 1916 epidemics is from Lavinder, Freeman, and Frost (*Pub. Health Bull. No. 91*, p. 109, 1918).

² The age incidence for the 1931 epidemic has been given to us through the courtesy of the New York City Health Department.

* Milbank Fund for Research on Poliomyelitis.

Limper, Thelander, and Shaw (*J. Prev. Med.*, 5:475, 1931) have called attention to the high incidence in California of persons 15 years of age and over in the 1930 epidemic. Although much the same areas of the state were affected as in 1925 and 1927, the adult percentage for the state as a whole in 1930 was 21.5, as compared with 18.3 in 1927; while the percentage of adult urban cases was 23.6 in 1930 as compared with 16.7 in 1927.

No figures are available which give the specific attack rates by age groups over a period of years. We know that there has been a marked change in the age make-up of the population even in the last ten years. Louis I. Dublin, in an analysis of the 1930 census, states that in 1930 the 0-4 age group in the United States was only 9.3 per cent of the total population, whereas in 1920 it was 10.9 per cent. Whether the attack rates for the various age groups will show so marked a trend as the percentage distribution remains to be seen.

The explanation is not known. Anderson (personal communication) has pointed out a similar trend in the age incidence of diphtheria in Massachusetts. This was quite marked until the extensive immunization of children of school age caused a temporary rise in the percentage of pre-school ages, but has recently again become visible. Thus it would appear that, whatever the explanation, this tendency is not peculiar to poliomyelitis.

Forsbeck and Luther suggest the possibility of an increased susceptibility of children born during the war years, but the figures for the 1931 epidemic would seem to cast doubt on such an explanation.

Aycock (personal communication) suggested to us that better diagnosis, a more general appreciation of the fact that poliomyelitis is not necessarily a disease of infants and young children, is a factor. While no one can doubt that better diagnosis must be reckoned with in this connection, the differences seem too great to be explained chiefly on such a basis, nor would such an explanation of course apply to diphtheria.

Jungeblut (personal communication) sees in the trend in age incidence in New York City a result of the drastic restriction of immigration in 1915. He argues that, since resistance to poliomyelitis is primarily a function of maturation, the age incidence in a heterogeneous population such as that of New York City will vary with the proportion of persons of northern and southern nationalities. The greater the percentage of slowly maturing north-Europeans, the higher will be the age incidence; the greater the percentage of quickly-maturing south-Europeans, the lower the age incidence. The immigration restriction excluded more particularly the south-Europeans. Recent experimental work (Jungeblut and Engle, *New York Acad. of Med., Pediatric Section*, Nov. 12, 1931), showing that virucidal substances may

be found in the blood after an artificially produced change in the endocrine balance of monkeys, would lend weight to this argument

The study of variations in age trends in poly-myelitis and in other diseases may yield data of rather far-reaching epidemiological significance

RENAL ANOMALIES

By JAMES R. LISA, M.D., and JACOB LEVINE, M.D., NEW YORK, N. Y.

From the Department of Pathology, City Hospital, W. I., Department of Hospitals, New York, N. Y.

RENAL anomalies are always of interest from the viewpoint of pathology, and frequently have a direct bearing on surgical procedures. They are found not infrequently during routine autopsies. The present report covers the anomalies found in 1200 consecutive autopsies performed at City Hospital, and includes all types with the exception of congenital cystic kidneys.

Anomalies of the blood vessels. Ten cases of anomalous vascular trees were found. Six were in males, four in females. Although anomalies of the veins are not infrequent in other parts of the body, those of the renal veins are extremely uncommon. Two cases were found, one with the left renal vein situated posterior to the aorta, another with a double right renal vein. Both these cases were associated with an anomalous arterial supply.

Supernumerary arteries were found much more frequently. In eight cases, this was unilateral, a double artery being present on the right in five cases, on the left in two, and in one other case, three being present on the left. In two cases, supernumerary arteries were present on both sides, two left and three right in one case, and bilaterally double in another. The mouths of the arteries usually were close together at the normal site. In two instances, the origin also was anomalous: one at the bifurcation of the aorta, the other midway between the mouth of inferior mesenteric artery and the aortic bifurcation. In both these cases, the supernumerary arteries were bilateral. The arteries usually entered the kidney near or at the hilum. In the two cases of anomalous origin, these arteries entered at the poles.

Anomalies of the ureters. Eleven cases were found, seven in males, four in females.

There were six cases of double pelvis, double ureter, and double ureteral orifice, five unilateral and one bilateral. Of the unilateral cases, three occurred on the left side and two on the right.

There were five cases of unilateral double pelvis, bifid ureter and single ureteral orifice. In three of the cases, this was present on the left, one of them being associated with a double ureter on the opposite side. The other two cases occurred on the right side. The points of junction of the bifid ureters varied from bladder wall to half the distance to kidney pelvis.

In one case, the right ureter emptied into the bladder at the center of the interureteral ridge.

Fusion of the kidneys. This was found in three cases.

One case, male, presented fusion of the lower poles to form a typical horse shoe kidney. This was associated with anomalies of the heart and aorta.

Two cases, one male and the other female, showed fusion of both kidneys at the normal site of the left kidney, the fused organs weighing 250 and 300 gms. Externally, the line of fusion was marked by a horizontal fibrous band, on section, it was indefinite. Each half had a separate pelvis and ureter, that of the upper half terminating at the left ureteral mouth, that of the lower at the right mouth. Evidently, from the arrangement of the pelvis and ureter, the lower half of the kidney mass corresponded to the right kidney. The adrenals were in their normal situations. In one case where the circulation was recorded, each half had a separate renal artery to the pelvis, the upper arising from the aorta at the level of the normal site, and the lower below the inferior mesenteric artery. The renal veins corresponded to the arteries and drained into the inferior vena cava.

Congenital vestigial kidney. One case, female, had only vestigial remains of the right kidney, the size of a thumb, with a non patent ureter. The left kidney weighed 250 gms and was normal as was its ureter.

Complete absence of kidneys. In one premature stillborn female infant there was no trace of kidneys or ureters. The bladder was normally placed, but with no ureteral orifices.

Congenital displacements of the kidneys. Three cases were found, two males, one female. They were all unilateral, two being on the left, one on the right. The kidneys were situated at the level of the iliac crest. The ureters were correspondingly shortened. One of these kidneys was supplied by a renal artery arising just above the bifurcation of the aorta.

Summary. Anomalies of the kidneys found in 1200 consecutive autopsies are summarized. They include all types except congenital cystic kidneys. Anomalies of the arteries, and pelvis and ureter were found the most common. Fusion of the kidneys with unilateral situation was unexpectedly more frequent than reports would indicate.

NEW YORK STATE JOURNAL OF MEDICINE

Published semi-monthly by the Medical Society of the State of New York under the auspices of the Committee on Publication.

Annual meeting, Hotel Statler, Buffalo, N. Y., May 23-25, 1932

NEWS REPORTS

The individual members of county medical societies, like those of all other organizations, are prone to let the officers do all the work, which, of course, is what the officers and committeemen are assigned to do. But the members are expected to know what the officers are doing.

This issue of the Journal contains a wealth of news regarding the activities of the State Society and the County organizations. An important news article is that describing the regional con-

ference conducted by the State Committee on Public Relations, in which the County Chairmen described the contacts which the County Committees on Public Relations are making with their local boards of supervisors, welfare officers, and other public officials. That by Dr. T. H. Cunningham, describing the work in Warren County, will be of special interest to members of the Public Relations Committees in other counties, and will inspire them to go and do likewise.

BROTHERHOOD

A doctor's attitude toward public health work is dependent largely on his temperament or inborn characteristics. Every man's nature is a combination of temperaments which all possess to a varying degree. The fundamental temperament essential in public health work is that of brotherhood. Some doctors have this attribute developed so highly that they throw themselves wholeheartedly into service for others with no regard for their own personal reward. A marked deficiency of brotherhood constitutes individualism or selfishness. The membership of every county medical society includes those in whom the attribute of brotherhood is highly developed, a few members with no outward evidence of its existence, and a main body of members in whom brotherhood and individualism are evenly balanced as in the average person.

Doctors rank with teachers and ministers of the Gospel in the possession of the trait of brotherhood. The reason is not so much that a medical training fosters that mental attribute as that the majority of medical students seek entrance into medical schools because they already possess the attribute and are impelled by it. Those who consider the study of medicine for gain usually enter other professions where honors and financial rewards are more evident.

Every doctor, no matter how individualistic his temperament, feels that the medical profession is under obligations to give health service to the community, and he is willing to subscribe to that creed as an abstract idea which is to be put into actual practice by his county and state medical societies.

The amount of service which a doctor is willing to give to his medical society depends largely on his temperament and sense of brotherhood. It is to the credit of the medical profession that the majority of doctors show their approval of the

work of their societies by their prompt payment of dues and their willingness to give specific service on committees.

It is a natural human trait to find fault with the attitude of other persons, but criticism is a two-edged sword that wounds its wielder as well as its intended victim. Arguments create dissensions, and a brotherhood founded on disputed ideas is practically impossible, for there are always two sides to a question and therefore, two opposing factors.

The idea of brotherhood to most persons implies personal friendliness, but in public health, as in all other great movements there often exists a brotherhood of an idea which may be so dominant that it submerges personal considerations. For example, insistence on the adoption of the platform "A county health department for every county" has threatened the rupture of personal friendships and delay in the execution of other desirable phases of public health work. When it comes to a test of strength, the brotherhood of personal friendship will triumph over that of an idea, no matter how disinterested its proponents may be.

Dissenters are not converted by argument and criticism, but by their personal respect and friendship for those who propose a different line of action and give good reasons for their opinions.

A dinner conference will settle a factional dispute more quickly and happily than a dozen public meetings will do. Nearly every dispute in a medical society is based on the dominance of an idea in the mind of a leader. Whether or not that idea shall result in dissension will depend largely on the personal attitude of that leader. If he has a sense of personal brotherhood and friendly consideration toward his fellow members, he will retain his influence even if he is unsuccessful in his proposal.

HUMANITY'S FRIEND—DR EDWARD M BURNS

The title of this editorial is also the title of an editorial in the *Poughkeepsie Evening Star* of February 1, 1932, in memory of Dr Edward M Burns, for thirty five years a beloved practitioner of the city. His medical colleagues subscribe to the sentiments of the editorial, and desire that publicity shall be given to one whose life exemplified the high ideals of the medical profession.

'He held a unique place in the city, a place he created for himself by his years of practice here. No one who went to him for help was turned away, no medical task was too arduous, no call too late, no trip too long. Anecdotes of his

service to this community's suffering humanity have grown about him for years, so that a legend of his good works will live beyond him until the last person whom he aided, or the last person who remembers such service, is gone.

"Modest retiring, hard working, Dr Burns went about his duties without ostentation yet always striving to relieve the suffering who turned to him for aid. And now he is gone—his life is only a memory. It is a memory, however, that will grow stronger and richer with the passage of time because he will be missed, and when people miss him they will recall the real worth of his services to this community."

POPULAR OPINION OF THE COUNTY MEDICAL SOCIETY

What do people say about your County Medical Society?

Do they realize that your Society is the advisor of the community in public health matters?

Do the people turn to the County Medical Society for final advice when lay health organizations propose clinics and consultations and lecture courses?

Let us ask another question: Do the people know that your County has a Medical Society? Go to the first ten business men that you meet in your home town, and ask each one this last question. The result will be startling.

One or two business men will say that they occasionally read accounts of meetings at which doctors get together to raise the prices on their calls.

Half a dozen men will say that they understand that the doctors want the county to build a tuberculosis hospital so that they will not have to get out of bed nights in order to minister to dying patients.

One or two will say that the president of the Society is quite a publicity hound, since he gets his name in the paper every month or two.

About one business man in the ten will show an intelligent knowledge of the aims and aspirations of the officers of the County Medical Society. The other nine will say that they "suppose" that the doctors have a county organization like that of the lawyers, or ministers, or school teachers; but only a small minority of business men realize that the County Medical Society is a vital, active force in the practice of public health in the community.

It is most encouraging that, when a body of business men, such as a board of trade, are instructed about a public health project, they give their hearty support to the proposal. The practice of public health by County Medical Societies is scarcely ten years old; and people are only now beginning to realize the wide scope and importance of the work. The progressive response of the people is most encouraging.

LOOKING BACKWARD

This Journal Twenty-five Years Ago.

The Clinical Laboratory:—This Journal of April, 1907, discusses the value of the laboratory in the practice of medicine, and advises the young doctor to make use of his laboratory knowledge and experience. The following editorial advice is being carried out to an extent that was not anticipated in 1907:

"As the younger man becomes more and more engaged with general practice he will give less time to the laboratory, but it is surprising how habits of accuracy in diagnosis cling to a man who has once practiced them. It is also surprising how difficult it is for a man who starts in practice 'by the rule of thumb,' to get away from his careless habits. About the worst thing that can happen to a young man is to enter immediately into a large and driving general practice before he has had a chance to get himself squarely oriented with regard to general medical work. The best results are to be secured by gradually growing out of the clinical laboratory into general practice.

"The equipment necessary for applying the modern methods of clinical diagnosis is neither formidable or out of the reach of the general practitioner. It does not require a complicated laboratory, although a laboratory is most desirable. A table for a microscope and its appurtenances is necessary. If there are no rooms adjacent to the consulting room, a small incubating oven may be set up in the kitchen. The apparatuses for blood counting and for determining blood pressure should be added to the clinical thermometer and the stethoscope. The important examinations to be made are of the sputum, the urine, stomach contents, feces, the blood, and bacteriological tests of mucous membrane discharges. The young men who are now being sent out to practice medicine have been taught these things, and they should practice them. The best conditions of general practice are served when the busy practitioner associates with him such a man. Their mutual interests will be helped by the cooperation."

MEDICAL PROGRESS

Metabolic Changes and Otosclerosis.—Clinical experience makes it evident, say H Behrendt and J Berberich, that otosclerosis must be regarded as a local disease that is closely related to the metabolism of the entire organism, but it has been difficult up to the present time to bring definite proof of this. The authors accordingly undertook to clear up the acid base equilibrium in otosclerosis. This could not be done by determining the hydrogen ion concentration of the blood, since it can easily be demonstrated that a diminished alkaline reserve may exist in presence of either a compensated acidosis or an alkalosis. First of all, therefore, the total carbon dioxide content of the serum was determined, and was found to average 18 volumes per cent lower than in healthy persons. This could only be interpreted as an indication of a diminished alkaline reserve, the cause of which, however, could not at once be recognized.

Uranalysis threw no light on the subject, nor did an examination of the different ingredients of the blood, until it came to tests for lactic acid, which was found to be 20-30 per cent lower than that in normal individuals, its average value being 7.4 mg per cent, as against a normal value of 10.4 mg per cent. This finding may therefore be accepted provisionally as an indication that an acidotic trend of the metabolism is more probable than an alkalotic. From this it was concluded that an acidotic state of metabolism in patients with otosclerosis is to be regarded as the expression, or the cause, of a general slowing down of the metabolism. In 16 cases of demonstrated otosclerosis a clear lowering of the basal metabolism could be established. It is of interest that 4 other cases which had been subjected to treatment with ultraviolet rays showed a basal metabolism not lowered but within the upper limit of normal. A glance over the totality of metabolic characteristics in otosclerosis gives rise to a very definite impression that some actual metabolic disease is present, constituting a constant and uniform disturbance of the state of equilibrium.

The only clinical finding that might be urged against an acidotic tendency is that of the electrical and mechanical hyperexcitability observed in these subjects. More recent studies, however, have shown that this is not the case, and that hyperexcitability is less frequently present than in normal individuals, so that this objection has no force. It is very evident therefore that endocrine disturbances are at the bottom of all these manifestations.—*Klinische Wochenschrift*, December 26, 1931

Some Points in Connection with the Treatment of Glaucoma.—R H Elliot claims that no case of glaucoma should be submitted to operation if the use of miotics, the employment of massage, and attention to the patient's general health suffice to arrest the course of the disease and to keep the case *in statu quo*. Of the two miotic drugs, pilocarpine is to be preferred to eserine in the majority of cases, as it causes less conjunctival irritation, does not give rise to the same measure of spasm and headache, and when suitably employed, maintains the necessary contraction of the pupil. When, however, it is a question of producing miosis as rapidly as possible in a patient with congestive glaucoma, eserine is the drug to employ. Pilocarpine should be used in the weakest doses that will maintain efficient miosis, and should be given the last thing at night, the first thing in the morning, and about three o'clock in the afternoon. This timing is highly important. If there is difficulty in maintaining miosis, this can best be combated by the use of silver collosol, alternated with hazeline eye drops. If miosis cannot be maintained, operative intervention may then become a necessity. Certain general rules should be impressed on every patient. He should avoid over-fatigue, get regular sleep, take regular meals, avoid alcoholic excesses, stooping and all sorts of strain, and, most important, all causes of anxiety. The following factors serve to guide the treatment: Tension of the eye, central visual acuity, curtailment of visual fields, enlargement of the blind spot, failing light sense, cupping of the optic disk. The use of belladonna should be avoided in all doubtful cases, especially when there is a family history of glaucoma. The use of cocaine or any other mydriatic in order to test an arterial pulse, by light pressure with the finger on the eyeball, is not worth the risk involved. In the past eighteen years the author has seen a number of cases in which glaucoma has been induced by the instillation of various mydriatic drugs including cocaine, homatropine, and atropine. The performance of iridectomy is vastly preferable. An arterial pulse is a sign which should fill the surgeon with anxiety. Until the sign has disappeared the patient should be kept in bed under the influence of sedatives, eserine should be used freely, a brisk purge should be given and leeches applied to the forehead. As soon as it is evident that nonoperative treatment is failing, operation should be performed without loss of time. The later the operation the worse the prognosis, though the latter is not hopeless even in very late cases.—*British Medical Journal*, December 26, 1931, ii, 3703

The Beginnings of Alcoholism.—W. Mayer-Gross points out, in the *Deutsche medizinische Wochenschrift* of November 27, 1931, that the point at which the alcohol habit becomes a disease cannot be determined simply by definition, but must rest on an empiric foundation. The fact that the damage done by alcohol does not as a rule become the object of medical treatment until much later in life, should not blind us to the fact that simple habit turns into addiction generally quite early. To understand the origin of alcoholism as a disease we must understand the significance of those disturbances and defects that are present in the consciousness of the drinker. Unable to face the conflicts of life, he uses alcohol to induce forgetfulness of the demands that reality makes upon him. By means of intoxication he is able to lose himself in a timeless condition, where past and future do not exist. It is customary to stress the special danger that attends the psychopath, especially of the passive type. But great caution is necessary in the assumption of a primary psychopathy as the basis of alcoholism. For chronic alcoholism produces permanent changes of character which strongly resemble psychopathy, making it extremely difficult to determine how much of these is attributable to a psychopathic anlage, and how much to the effect of alcoholic poison. But it would be far from the truth to take the view that only individuals who are psychically inferior can become alcoholics. This is seen from the fact that only a small proportion of women become addicted to alcoholism, yet psychopathic anlagen are no less frequent in them than in men. It appears that those physicians who are not psychiatrists are as a rule slow to recognize alcohol as the etiologic factor in the disease to which it leads; they appear to be suffering with an ineradicable scotoma, that is unwilling to see the obvious. The point of attack for alcoholism lies in prophylaxis. Alcoholism is a community disease, its beginnings must be systematically attacked by the cooperation of physicians with boards of health, in the same way that this is done in connection with other community diseases, such as tuberculosis.

Rheumatic Heart Disease.—David Davis and Soma Weiss, writing in the *American Heart Journal*, December, 1931, vii, 2, present a study of the incidence and rôle of rheumatic heart disease in the causation of death in 5,215 consecutive necropsies. They have correlated the morphological findings and clinical data, for the reason that statistics based on clinical data alone may fail to include a considerable number of cases. Of the 5,215 necropsy records of patients from the poorer class cared for in the Boston City Hospital between 1905 and 1929 inclusive, rheumatic heart disease was revealed in 474, or 9.1 per cent of the cases. Of this group 56.6 per cent were

males and 43.4 per cent were females. The sex distribution in the total necropsy examinations was 62 per cent for males and 38 per cent for females. Thus rheumatic heart disease was slightly more prevalent among the males. Of the total number with rheumatic heart disease 3.8 per cent were Negroes; 8 per cent of the autopsied patients were Negroes. This would indicate that rheumatic heart disease occurs about half as frequently among Negroes living in New England as among the white race. Rheumatic heart disease was directly responsible for death in 164 instances, or 34.5 per cent of the total group with this affection. In an additional group of 41 cases, corresponding to 8.6 per cent of all the cases in this group, subacute bacterial endocarditis was superimposed on rheumatic heart disease. In 21 cases, or 4.4 per cent of the cases in this group, malignant endocarditis developed in association with rheumatic heart disease. As the subacute and primary acute endocarditis developed on previously damaged rheumatic valves, in this group, representing 13 per cent of all cases with rheumatic heart disease, death was caused indirectly by rheumatic heart disease. In 205 cases, or 43.2 per cent of the cases with rheumatic heart disease, the character of the cardiac involvement was such that the lesion did not contribute to death. The study shows that rheumatic heart disease is surprisingly prevalent among the poorer section of the population of Boston. Its frequency (9.1 per cent) approaches that of carcinoma (10.4 per cent). Rheumatic heart disease frequently exists, however, without causing obvious impairment of the circulation.

Anemia of Alimentary Origin in Childhood.—According to Louise Weill, the clinical study of anemias of alimentary origin is a complex matter. Experiments are necessary, and these demand a rigorously careful technique. Blood examinations carried out during periods of inanition do not show anemia, but after a few days of re-alimentation a hypoglobulia and a fall of hemoglobin are observed. Clinically, subjects who have been suffering with inanition remain pale for a long time. The quality of the alimentation is also of great importance, carbohydrates being of no value for blood regeneration, and excess of fats having an anematizing effect. The exclusive use of albuminoids is harmful, but these substances are indispensable for normal blood regeneration. Certain amino-acids would seem to be more active than others. Dehydration represents a cause of error. Iron is indispensable, and its lack produces an anemia of chlorotic type, frequently seen in infants who have been fed too long exclusively on cow's milk, this product being very poor in iron. Treatment with iron in large doses gives excellent results, and copper is said to have a good effect, experimentally. Vitamins A and B seem

to have a slight effect upon the blood, and vitamin C has an undeniable one. Its absence causes scorbutic anemia or the anemia of pre-avitaminosis, which is favored by the very early age and growth of the infant. Iron alone produces no results here. Lemon juice has a very good effect, and works rapidly. Vitamin D, so far as we can at present observe, does not appear to have any direct effect on the blood. Lack of iron is the main factor in producing anemia in the child fed exclusively on cow's milk. Young infants fed exclusively on goat's milk suffer with severe anemia, accompanied by hypotrophy, the pathogenesis of which is not well understood. Experimentally, the cause does not appear to lie in absence of vitamin C or of iron, nor in hypoalbumination. Liver acts rapidly upon scorbutic anemia, but only slowly upon the lesions in the bones. Hence in severe cases it must not be substituted, but must be given in association with lemon juice. Hypoalbumination is what has to be feared in these cases; the diet must be varied and perfectly balanced. In fact, balance must be the guiding principle throughout treatment.—*Journal de Médecine de Lyon*, January 5, 1932.

Aplona, a Simplification and Improvement of the Heisler-Moro Apple Diet.—Siegfried Wolff, writing in the *Deutsche medizinische Wochenschrift* of December 25, 1931, recalls the good results already obtained by use of the Heisler-Moro method of administering raw apples reduced to a pulp, for the control of diarrhea. Long observation, however, revealed that the results are uneven, some kinds of apples lending themselves better to the method than others. Furthermore, it is not always possible, at all seasons of the year, to obtain the apples best suited for this use. For this reason it was desirable to provide a standard product, if possible, that should be available irrespective of the time of year. Such a product can now be had, in the shape of aplona, an unadulterated apple powder, 100 grams of which are equivalent to 1000 gm. fresh apples. This powder can be given in warm water or tea, or in barley or rice water, after standing 5 minutes in a hot water bath, with care that the temperature shall not exceed 50° C. (122° F.). In this time the powder swells, and can then be taken hot or cold, sweetened with or without saccharine, according to taste. The flavor is highly agreeable, quite characteristic of apple, and is enjoyed by both children and adults. A further advantage of this method of administration is that it can be used in any concentration desired, from 1 to 10 per cent. Wolff begins with a dosage, for infants under 6 months old, of 100 grams of a 2 per cent concentration 6 times a day; infants over that age receive the same dosage of a 4 per cent preparation. Older children are given 150 grams of a 4-6 per cent solution 5 times a day;

but there is naturally no need of strict schematization in the dosage. On both the second and the third day the dosage is increased, both in amount and in concentration; in most cases a part of the meal may by the third day consist of other forms of diet, of a light nature. It has been Wolff's experience that the stools always become formed on the second day, and only in exceptional cases has it been necessary to give aplona after the fourth day. Its chief indication is in cases of acute dyspepsia. It has given excellent results in parenteral dyspepsias in association with grip, pneumonia, otitis, and infectious icterus. The author does not mention ordinary applesauce which would a priori appear to be the same in action as powdered apple.

Abdominal Discomfort.—The word discomfort has been chosen by A. E. Russell to embrace the earliest subjective sensations that give warning of the onset of serious disease. Some of the grossest disturbances within the abdomen, namely, ascites, tuberculous peritonitis, enlargement of the spleen or of the liver, deep-seated abscess, and malignant growths, may give rise to little pain. The view that abdominal pain must be due to stimulation of the afferent visceral fibers and is not felt in the viscera at all, but is referred to more superficial structures, has not been substantiated. The existence of real visceral pain is again recognized. Of the structures contained within the abdomen the peritoneum lining the anterior abdominal wall is the most sensitive. The alimentary canal is insensitive to tactile stimuli and is very inadequately stimulated by heat, except as regards the esophagus and anal canal. The rôle of hydrochloric acid in causing pain is somewhat uncertain, but since it keeps an ulcer from healing, the most successful treatment aims at lowering the acidity of the stomach contents. Intestinal gas as a cause of discomfort is worthy of more attention than it receives. Any degree of distention beyond the constant or normal causes a feeling of fullness and discomfort. On the other hand, a diminution of gas below normal may cause discomfort by permitting the close apposition of the mucous membrane with obliteration of the canal. The position of pain or discomfort is of great diagnostic significance, and in the main it is felt in the region of the part involved. In certain cases pain and discomfort may be experienced in a locality rather remote from the cause; thus renal pain may start in the groin and appendicular pain is often umbilical in situation, shifting to the right iliac region when the peritoneum becomes involved. Hepatic and splenic pains and discomforts are felt in their respective hypochondriac regions and pancreatic pain in the epigastrium. Pain in the ascending and descending colon is accurately localized; the mobility of the transverse colon diminishes the

NEWS NOTES

COMMITTEE ON PUBLIC RELATIONS

A regular monthly meeting of the Committee on Public Relations of the Medical Society of the State of New York was held on Thursday, February 18, in the Albany office of the State Society, 100 State Street. There were present Dr. J. E. Sadlier, chairman, Dr. G. M. Fisher, Utica, Dr. O. W. H. Mitchell, Syracuse, Dr. A. J. Hambrook, Troy, Dr. W. D. Johnson, Batavia, President of the State Medical Society, Dr. F. F. Farmer, Chairman of the Committee on Public Health and Medical Education, and Dr. J. S. Lawrence, Executive Officer.

The morning session was devoted principally to a conference with Dr. W. A. Howe, and other representatives of the State Department of Education on the subject of the medical inspection of school children, with particular reference to the recommendation of the Governor's Health Commission that the examinations of school children be made at longer intervals than one year, as required by the present Education Law, but that the examinations be more thorough (see this Journal October 1, 1931, page 1216).

It was finally decided that the Committee on Public Relations and the Committee on Public Health should take up the subject of the medical examination of school children with each county medical society, and should urge it to devise means of arousing the interest of family physicians in the examinations.

The Chairman reported on action of the House of Delegates at its special meeting on January 14, requesting the Public Health Council of the State Department of Health to publish proposed amendments to the State Sanitary Code, in order to give physicians and others opportunities to discuss them before their final adoption (see this Journal February 15, 1932, page 224). In compliance with that request the Council of the State Department of Health had published in the February eighth issue of *Health News* a proposed amendment to the State Sanitary Code, defining the qualifications for health officers. This amendment proposes to classify health officers in two grades.

Grade one includes health officers of counties and those of cities of over 50,000 population. Their qualifications shall consist of either an approved course in public health of two years' residence, and one or two years' practical experience in public health work; or

five years of full-time practical experience in a responsible administrative public health position.

Grade two health officers include those of smaller cities, and those of villages and towns and consolidated districts. Their qualifications remain practically as at present, including the correspondence courses and short periods of practical instruction.

The informal discussion of the chairman's report showed that the members of the Public Relations Committee were of the opinion that if the proposed regulation were adopted, physicians in active family practice would find it difficult or impossible to qualify as county commissioners of health. The committee will take this subject up with the Public Health Council of the State Department of Health.

The afternoon session was devoted to a regional conference of the Chairmen of the Public Relations Committees of fifteen counties about Albany. Fifteen counties were included in the call, and nine were represented as follows:

Albany—Dr. J. N. Vander Veer
Greene—Dr. A. B. Daley
Schenectady—Dr. W. C. Treder
Montgomery—Dr. Charles Stover and his entire committee, including Drs. Collier, Ormsby, Hicks and Pierce.
Fulton—Dr. H. H. Oaksford
Warren—Dr. T. H. Cunningham
Clinton—Dr. E. S. McDowell
Schoharie—Dr. D. W. Beard
Saratoga—Dr. M. J. Magovern
Dr. M. F. Murray of Otsego County, and Dr. C. A. Hemstreet of Rensselaer County, sent their regrets at their inability to attend on account of sickness.

Dr. Vander Veer reported that the Albany County committee was preparing a new survey of the county. The previous one was made in 1927.

Dr. McDowell reported that the Clinton County committee had reached a satisfactory agreement with the welfare authorities of the county. He also reported that the committee had completed a survey of the obstetrical problems and conditions in the county.

Dr. Oaksford's report on Fulton County showed that his committee had made an arrangement with Montgomery County to take care of their tuberculosis patients. A close relationship is maintained with the activities

of the Gloversville city physician who refers all work possible to local physicians. He further stated that his society is opposed to the organization of county health units by mandatory law, and closed his remarks by saying that "we should be in the driver's seat" in public health matters.

Dr. Daley of Greene County reported as follows: "While our Public Relations Committee of Greene County has not accomplished a great deal as yet in the way of putting into effect a definite program with the various welfare agencies and lay organizations throughout the county, the committee has had several interesting and well attended meetings at which matters of mutual interest to the medical profession and the laity at large have been discussed. As a result of these conferences, the Medical Society of the County, at one of its regular meetings last fall, discussed and favorably acted upon a set of resolutions drafted by our committee relative to a more satisfactory and workable program involving the relationship between the profession and the laity, together with the Board of Supervisors of the county, and calling for a definite and harmonious cooperation between all interests concerned. A copy of these resolutions was forwarded to the Supervisors for their consideration and approval. Questions regarding the examination of the pre-school child, the diphtheria prevention movement, and the advisable administration thereof, together with the consideration of other various problems affecting the public health and welfare of the county, are now receiving the attention of the committee."

Dr. Stover reported that the board of supervisors of Montgomery County influenced by the fate of the Wicks-Hutchinson bill, had passed a resolution hostile to the organization of a county health unit. He felt it would be unwise at present to press an extra expense on the county, but his committee will continue to develop an educational interest in the organization of a county health unit. His committee has not, as a rule, taken a great interest in the activities of the voluntary agencies that work in the county. He feels that the influence of the County Medical Society is such that it can accomplish what it decides to be essential.

Dr. Magovern said that the Saratoga County Society does not feel it wise to have the public health work organized under the county health unit plan, and suggested that further study by the physicians is essential. He also stated that in the near future an attempt will be made to place before the Board of Supervisors a plan whereby physicians will be compensated for services rendered indigent cases in the hospitals.

Dr. Treder of Schenectady County reported that there has been some difficulty with the employment of public health nurses. The board of supervisors had cut out of their budget \$6,000 which was appropriated for the employment of public health nurses, but the item was restored when the Nurses' Association objected. The physicians are receiving satisfactory cooperation from the Commissioner of Public Welfare. His committee is now helping to solve a situation which has arisen in regard to the superintendent of the County Tuberculosis Sanitarium.

Dr. Beard of Schoharie County said that relations between the physicians and the public had been very satisfactory for the past few years. The secretary of the County Society is a member of the County Red Cross Committee, which supervises the activities of the county nurse. The public welfare law operated well last year. On the whole, the profession in Schoharie County has the support of the population to a great extent.

Dr. Hambrook reported for Dr. Hemstreet that in Rensselaer County the welfare officers and physicians are cooperating very agreeably; and that the county outside of Troy has four district public health nurses who conduct tuberculosis clinics and pre-natal clinics. The general sentiment in the county is in favor of organization on the county health unit plan.

Dr. T. H. Cunningham, of Glens Falls, read a comprehensive report on the public relations of the medical profession of Warren County, to the other public health organizations of the county. (This report is so full and comprehensive that it is printed as a separate article immediately following this report.—Editor.)

J. E. SADLIER,
Chairman.

PUBLIC RELATIONS IN WARREN COUNTY

The following report, on the relations of the medical profession of Warren County, N. Y., to public health, was given by Dr. Thomas H. Cunningham of Glens Falls, Chairman of the Public Relations Committee of the Warren County Medical Society, at a regional conference of the chairmen of the committees of twelve counties with the Committee on Public Relations of the Medical Society of the State of New York, held in Albany on February eighteenth, 1932. The report supplements "Public Relations Survey No. 17,—Warren County," published in this Journal of December 1, 1930, page 1436. Warren County has a population of 42,000 and its County Medical Society has 44 members.

We have been trying for three years to make the Warren County Medical Society an important factor in all public health and welfare work. We have tried to take a part in everything that had to do with public health or welfare in the county, and our society is now being recognized as an organization to be consulted in regard to all these matters.

We have sent representatives to act with and confer with the directors of many of the public health and welfare organizations, we have written letters to the newspapers, and we have appeared before many lay organizations in these efforts. The physicians doing these things have always tried to have it clearly understood that they were not acting as individuals, but simply as the representatives of the Warren County Medical Society; and we have explained time and again that our medical society is our official organization, and that it bears the same relationship to the physicians of our county that the Bar Association bears to the lawyers of the county.

We have been trying to get a county department of health established in Warren for almost three years. We have wanted this because we are sure that a county unit offers us the only way of systematizing the public health and welfare work in our county, and of regulating it so that there will be no infringement on the field which should belong to the local medical profession.

We are sure that a county unit will give our citizens the best possible results from their expenditures for public health efforts; and we feel, too, that our society can exert enough pressure upon the county board of health and the county health officer so that our interests will be protected and our incomes will not suffer as a result of their work. Such a statement may give the impression that our efforts are based on selfish motives; but actually they are not, because we are sure that our local medical profession will deteriorate unless it can enjoy an income great enough to permit it to do post-graduate work, take medical journals, buy diagnostic equipment, and do all of the other costly things which are needed to keep a physician abreast of the times.

The economy wave which is going hand in hand with our depression is holding up this county health unit. Our medical society has sent representatives to speak before the county Board of Supervisors, the Common Council of the City of Glens Falls, and many organizations in the county. We have interested about four hundred prominent citizens in the matter to the extent that they have formed an organization for the pur-

pose of promoting a county health unit. At the present time committees from the supervisors and from the common council of Glens Falls are considering ways and means for establishing a county unit. These committees are fearful, however, of increasing the tax rate, and it is possible that favorable action on the matter may be deferred for some little time.

Our society has received a great deal of excellent advertising from our efforts, and almost every citizen of the county now knows that the county has an organized medical profession which is capable of thinking, and of asking for what is best for the citizens at large.

At the meeting last year our medical society succeeded in gaining control of a local eye clinic which had been for years under the control of local optometrists. Our society took over the professional side of that clinic, and provided three eye surgeons who have organized it in exactly the same way that they conduct the eye service in our hospital wards. They have divided the year into terms of service, and they have elected a representative who speaks for them at meetings with the Board of Trustees of the Blind Association which covers not only our own county, but the counties of Washington and Saratoga as well.

Our medical society has stated to the trustees of the Blind Association that we are glad to extend this service to indigents. We have stated also, however, that we do not care to give clinic service to those who are able to go to the local eye specialists' offices as private patients. There is a very definite understanding that, if the attending eye specialists find at any time that they are being imposed upon in this matter, the county medical society will withdraw its support from the clinic. We have explained that there will be no rows and no discussions in regard to this matter, but that our three eye specialists reserve the right to withdraw quietly from the clinic at any time that they may feel that they are not being fairly used in this matter of giving their services only to patients who are not able to pay for them.

We have had considerable trouble with some of the other clinics in Warren County. As an example the orthopedic clinic conducted by the New York State Board of Health meets at irregular intervals in Glens Falls. Just prior to a clinic day last fall an advertisement was inserted by someone in our local newspapers urging that all citizens with orthopedic troubles take advantage of this free clinic. It was stated in the advertisement that all were welcome, and that people with

flat feet were especially urged to attend the clinic and secure relief for that condition. There was to be no charge made for the services of course and there was no implication that the services were to be restricted to our indigent citizens.

Our committee wrote Doctor Parran, State Commissioner of Health, enclosing some of these offensive advertisements, and pointing out how unfair such a stand was to the local medical profession. We suggested that the New York State Health Department could hardly expect cooperation from a local medical profession when it was entering the local field in such unfair competition and suggested that a conference be held to try and straighten out the matter. Doctor Parran came to Glens Falls and attended a dinner which we gave there and at which were present most of the local physicians who had any complaints to make about any of the clinics. The discussion was general and was not confined to the orthopedic clinic. The whole clinic situation was reviewed, and we tried to make Doctor Parran understand our attitude toward the prenatal clinic for example and much of the other clinic work. The meeting closed amicably, and there was a feeling on both sides that many of our difficulties had been straightened out. A scheme was submitted by us to Doctor Parran which we hope will eventually smooth out the orthopedic situation locally.

Our committee pointed out to Doctor Parran that our local surgeons could not compete with his clinic as he was conducting it. We pointed out that his clinic was headed by an expert orthopedist, that he had working with him an expert orthopedic nurse, that he had all of the public health and welfare agencies acting as advertising agents, and that he offered his services to all free of charge and regardless of their financial status. We pointed out to Doctor Parran that this was going to result in our local surgeons doing less and less orthopedic work and therefore becoming less and less competent to do that special branch of work.

We pointed out too that, in case the State should ever withdraw its financial support for that particular clinic, it would result in the county of Warren being left without any surgeons with orthopedic training, and that we believed that the harm which would thus result would more than offset the benefits that the citizens are now deriving from his free orthopedic clinic.

We suggested that our local surgeons be allowed to select one of their number who would work with Doctor Craig, orthopedic surgeon of the Department of Health, as his assistant at the clinic. We offered to secure an appointment as consulting orthopedist for Doctor Craig on our local hospital staff, and this would give him local operating room privileges. We urged that Doctor Craig then do as much as possible of his op-

erating in our local hospital, and that he use the local surgeon as his assistant for these operations and leave the cases in his charge when Doctor Craig left the city. We suggested also that we would give him a man who had had at least twenty years' training as an attending surgeon at our hospital, and who was also a Fellow of the American College of Surgeons; and we suggested that under these conditions Doctor Craig might be willing to permit this man to operate on the less serious cases and that Doctor Craig might then act as assistant or as consultant at such operations. Our idea was that we could thus keep these cases in our city, and that at least one of our surgeons would keep in touch with orthopedic work. It would also give us an opportunity of training one or more of our local nurses in orthopedic work, and would generally speak for betterment for our local profession and our citizens. Doctor Parran accepted our plan and our local surgeons have selected one of their number to act as their representative. He and Doctor Craig of the State Department have had some correspondence in regard to arranging a scheme for work. I do not know just how far the matter has progressed, but I hope that in the not too distant future we shall have an orthopedic clinic functioning in the manner which I have outlined.

Our Parent-Teachers Association had their second Round-Up Week last summer, and the head of the organization communicated with our committee and stated that many of the parents who wished to have their children examined had said that they were not in a position at just this time to pay for such an examination. The Association wanted to know what clinic they should send these children to in order to have this work done.

Our committee asked for a list of these indigent families, and for the names of their family physicians. We then communicated the facts to the family physicians, and they all offered to make such examinations free of charge. In conversation with some of them later I was told that the family physicians approved of our procedure because it kept these families from the clinics, and it helped the family doctor to hold his practice together in our present depression.

Last year the Warren County Tuberculosis Society made a survey in our county to discover how many indigent children in the county could be grouped as predisposed tuberculous children. It found about two hundred who required removal of tonsils and adenoids, and other minor nose and throat procedures in order to make them less susceptible to tuberculous infection.

The head of that society communicated with our committee and asked how it could be arranged for these children to enter the wards of our local hospital for operation. We found upon investigation that not all of these children were actually entitled to ward care, because some of the

parents were able to pay something for these services, even though none of the parents was able to pay full fees either to the surgeon or to the hospital. We brought three of our local nose and throat surgeons into contact with the Tuberculosis Society and suggested that they work out a scheme whereby the Tuberculosis Society would make arrangements to have this work done and would find out just exactly what the greatest sum was that each parent could afford to pay for the operation and for the hospital care. We suggested that the society collect this money and hold it in a lump sum to pay all of the expenses incurred. We suggested, too, that the hospital accept these children at a small flat fee, and pointed out that the hospital would lose less money by so doing than by having the children go into the wards. We suggested, too, that whatever lump sum was left after the hospital expenses were paid be divided into three parts, and that each of the three operating nose and throat surgeons be given one of these sums for his services. In this way the children had necessary care and the hospital, and the nose and throat surgeons received something even though they did not get their full fees. We all felt that it was better for these parents to pay what they could, instead of to go into the wards as charity cases.

Last spring our committee arranged a meeting between the Welfare Commissioners of Warren, Washington, and Saratoga Counties, and our medical profession. At that meeting the provisions of the present Welfare Act were discussed and we tried to impress upon the commissioners that the medical profession should be compensated for services to the indigents under their care.

It has not yet resulted in much money for the local profession, because of the fact that the budgets for the counties had already been made out. The meeting was very satisfactory however in that we secured evidences of cooperation from the commissioners; and we are sure that in time a very satisfactory working basis will be established between them and our physicians. All of the commissioners conceded that physicians should be compensated for their work among the indigent and it was simply a question of devising ways and means for working it out satisfactorily.

Some months ago the president of our local Young Men's Christian Association asked for a meeting with our committee. He and his physical director came to the meeting and stated that the physical director was very anxious to install in the building an equipment of sunshine lamps, electric cabinets, and some other physio-therapy equipment in order to give treatments to the patrons of the gymnasium. We discussed that matter at the meeting and stated that we would write a letter to them a few days later after a more careful consideration of the request. In our letter we pointed out the dangers attached to the

indiscriminate use of these therapeutic agents, and we pointed out also that the "Y" could not conscientiously use them without having a competent physician or nurse in charge in order to prevent harm being done.

Following the receipt of this letter the trustees of the Y.M.C.A. called a meeting and decided not to install the equipment. The president of the board wrote us a letter thanking us for our advice and consideration and expressing pleasure at having been able to turn to us in this matter.

I trust Mr. Chairman that you and the gentlemen present are not thinking I am taking up too much time in discussing unimportant matters. I am assuming, and I hope rightly, that you are interested in all of the trivial details that have attended the work of our committee. We started our work without any precedent to guide us, and we have simply done our best to keep ourselves as much as possible before the public and to associate ourselves in the minds of the public with these various welfare and public health matters in a consulting capacity.

We have lost no opportunity to put the Warren County Medical Society into the newspapers. For example, my committee wrote the editor of one of our local papers a letter of commendation because of an editorial which he wrote and printed during our poliomyelitis epidemic. In that editorial he pointed out that there was no use in our citizens becoming too greatly alarmed, and that safety lay in consulting with the family physician just the moment that the child showed any symptoms of any sort that would indicate any oncoming disease. Our committee congratulated him on his sane viewpoint, and stated that we hoped that his readers would pay careful attention to what he had said. He printed our letter on the front page of his paper the following day, and seemed very proud of the fact that he had been commended by the Warren County Medical Society.

The most ambitious project that our committee has tackled is the securing of a new hospital for our city. We secured a great deal of reliable data concerning the number of people who should be dependent upon our city for hospital care, that is the number who should normally fall into our hospital district. We found that our city should normally be giving hospital service to a district containing about 75,000 permanent citizens; and we found, too, that this number was probably doubled by the summer population which comes to Lake George and the lower Adirondacks in our vicinity.

We then communicated with the American Hospital Association and found out the number of beds that should be normally required to service a population of this size and character. We also secured a very exhaustive summary of the hospital accommodations which our city is now offering.

All of these facts were assembled in a report to the medical society. This report urged that the medical society call the attention of the citizens of our city to these facts, and that the citizens be urged to construct another hospital of a considerable bed capacity in order to meet this normal demand more adequately.

We also urged that the medical society ask the religious and service organizations of our city to interest themselves in the matter, and that the Commercial Association and business men be also asked to investigate the business side of it just as they might wish to investigate the financial possibilities of a new industry which was thinking of moving into our city.

We pointed out the beneficial effects that better hospital accommodations would have upon the local medical profession, and the secondary benefits that would thereby be derived by the citizens at large. We also urged that changes be made in our present hospital nursing system, that no wards be constructed in the new hospital, and that several physicians nominated by the medical society be placed upon the Board of Trustees of the institution.

A resolution was passed at the meeting at which this report was given endorsing the report and asking that it be published in our newspapers. Our newspapers were very glad to feature the entire report as front page news, and the project secured a great deal of publicity because of this, and it has aroused a very favorable reaction on the part of our citizens.

We do not expect of course that such a hospital will be built immediately. We pointed out in the article that we expected that it would be at least two or three years before a site was selected and plans drawn, and we stated also that we realized that the present depression would probably interfere somewhat in starting the project.

We expect however that we will get this new hospital and we are planning from time to time to have prominent citizens write the newspapers questioning some of our statements in order that we may answer them and keep the matter alive and before the public.

One of our physicians of standing was sued for malpractice a short time ago. The local profession felt that the suit was a most unjust one, and we are all very anxious to discourage the bringing of unjust suits. Our committee communicated with the attorney for the New York State Medical Society, and stated that any or all of the four attending surgeons at our hospital would be glad to cooperate with him in giving expert testimony in this case. We stated that we made this offer because we feared that the physician who was being sued might have some delicacy about asking for our backing. The state attorney seemed pleased at the cooperative spirit shown by our society and wrote stating that he would be glad to avail himself of it if the case comes up for trial.

THOMAS H. CUNNINGHAM, M.D.

EARLY DIAGNOSIS OF TUBERCULOSIS

The State Department of Health is confronted with a many-sided problem in its anti-tuberculosis work, and realizes its dependence on family physicians for success. The Department therefore appeals to the general practitioner to take an active part in an Early Diagnosis Campaign, the slogan of which is

"Tuberculosis comes from tuberculosis. Every case comes from another."

Such a slogan is broad in its implication, but it emphasizes principally the need for prevention. The family doctor plays a most important role in the further solution of the tuberculosis problem.

If more progress is to be made in the more general application of known methods of combating the disease, physicians must keep uppermost in their minds the fact that prophylaxis is as important as therapeutics. Although this campaign last only a month, the tubercle bacillus works every day in the year. Campaigns are of

value, but continuity of thought, word, and action throughout the year must prevail if we are to hope for encouraging results.

The fundamentals of adequate tuberculosis work are case-finding, follow-up, treatment, and public health education. Each of these essential elements must assume a conspicuous place in our prevention program. Lack of the coordinated machinery with which to carry on these services cannot but affect the results unfavorably.

In the light of experience, it is time for health officials and physicians to talk about the number of *households* in which tuberculosis is present, rather than the number of *cases*. Every physician realizes that tuberculosis generally is a family disease, and is far more than a personal problem of an individual patient. Environmental factors in family associations provide an opportunity second to none for massive infection. Such infection is likely to cause disease with its resultant medical, social, and economic handicaps.

Case-finding is the keystone of tuberculosis control; and closely allied with this *case-reporting*. Early diagnosis and prompt notification of cases are of paramount importance in the successful conduct of any control program.

Treatment and education go hand in hand,—treatment for the *patient*, and prophylactic education for the *patient*, *family* and *community*. Sanatorium treatment and education are to be considered in almost every case.

Adequate follow-up work is always essential with both patients and contacts. In this field of endeavor the public health nurse is a valuable aid to physicians. Equally important is the coordinated effort of the practicing physicians and public health officials, including those of the sanatoria and unofficial agencies.

"*Every Case Comes from Another*" is worthy of repetition, and reiterated by all concerned with the health and welfare of the people. Who is in a better position effectively to promote measures which will reduce further the prevailing morbidity and mortality rates, than the family doctor? Many physicians are profoundly interested in preventive tuberculosis work. They are taking an active part in this significant medical and social problem. However, there is room for improvement. It is to be hoped that these *Early Diagnosis Campaigns* may result in a more general and thorough application of these basic principles of tuberculosis control.

ROBERT E. PLUNKETT,
Director, Division of Tuberculosis,
N. Y. State Department of Health.

LEGISLATIVE RÉSUMÉ FOR 1932

The legislature closed its shortest session on record on Friday, March 11th, 1932. Until the last minute we were not certain but that the osteopaths might be successful in having their bill advanced and, therefore, we were obliged to keep in close touch with the session all the while.

We have been informed that the Regents, by resolution, have decided to require that the osteopaths must present after 1935 two years' pre-medical work when entering the state board examinations. That means that all persons who expect to practice osteopathy in New York State in the future must now begin their two years' pre-medical school work. Osteopathy will no longer offer the student a short-cut to the practice of medicine; thus a part of the osteopathy problem will be solved, but without doubt efforts will be made again next year by those who are practicing osteopathy in the state, to have their privileges extended. There is an honest desire on the part of a number of the osteopaths to be taught pharmacology and *materia medica*, and it seems to us that the medical schools might make some provision by which osteopaths desiring to familiarize themselves with drugs and their prescriptions, could be given an opportunity to take up such post-graduate work.

A physiotherapy bill was introduced, but received no support. No chiropractic bill was introduced. We are informed that efforts were made to do so, but the chiropractors were discouraged by conversations with the legislators.

No anti-vaccination bill was introduced this year, nor birth control bill, but the anti-vivisection bill proved to be more troublesome than usual. A disaffection occurred among the anti-vivisectionists and resulted in a second bill being

introduced in the Assembly and a companion in the Senate. The ambitious young ladies who sponsored this second bill proved themselves to be most aggressive lobbyists. They presented petitions signed by twenty thousand voters of the state, asking for the advancement of their bill, and would have succeeded had they been able to show to the satisfaction of the legislators that the present law protecting the dog is being violated. These ladies were not discouraged, but let it be widely known that they shall immediately begin a campaign program which will be carried to every section of the state, calling for support of their measure for next year. They threaten to campaign actively against the return of certain Assemblymen. It is highly important, therefore, that the physicians should take a more active part in informing the public of the true facts regarding the services rendered by the dog in our experimental work. The anti-vivisectionists make their greatest progress through enlisting the assistance of the humane societies. Their appeal to the people is, unfortunately, not based upon honest data. The gruesome illustrations which they circulate very widely are mostly taken from a German catalogue of apparatus and equipment, issued twenty-five or more years ago. Many of the statements that they have gathered from medical journals regarding the use of dogs, are taken from journals and text-books, some of them fifty years old; for instance, they brought to the chairman of the Senate Public Health Committee, for his study, a book on physiology published in 1888.

Some of these women do not hesitate to say that their friendship for the dog is such that they do not feel dogs should be sacrificed, even

though by so doing they would save the lives of babies. The sincerity of their friendship for the dog can be questioned on the ground that their greatest interest seems to be in taking the dog out of the experimental laboratory. They are not interested, according to their own statement, in preventing dogs from being summarily electrocuted or asphyxiated in pounds by humane societies; they have no interest whatever in securing the immunization of dogs, generally, against rabies or distemper; they do not wish information as to the conditions under which dogs are spayed; they are not even interested in securing legislation such as Assemblyman Cuvillier introduced this year, bringing a heavy penalty upon persons who deliberately run dogs down with their automobiles or abandon dogs they have had as pets. These people should truthfully be considered as opposed to what they term "vivisection," and should not be permitted to masquerade as dog lovers, because, upon being pressed, their leader admitted that were this legislation enacted, their organization would return in another year, asking that similar legislation be enacted for all animals.

In this connection, it is most disheartening to learn that there are physicians in the state who encourage these people by saying that dogs are not necessary for laboratory work and that they, personally, never profited from the use of dogs. The hospital lien bill in which we were interested, was killed in committee. Its opponents did not deny that there is need for such legislation, but they were opposed to the wording of the two bills which were introduced this year. It is to be hoped that in another year we can arrive at a wording that will be acceptable to everybody.

The bills that would permit injured workmen free choice of surgeon, which were before the legislature last year, were reintroduced, but they received less consideration than last year, prob-

ably because the report which the special commission appointed to investigate problems affecting workmen's compensation, recommended against free choice, and labor organizations, likewise, opposed such legislation.

Three bills offering amendments to the Workmen's Compensation Law, resulting from the report of this special commission, were introduced just before the close of the session, but did not get out of committee.

Our relations with the legislature were unusually pleasant this year. We felt the legislators appreciated that we were always acting in the interests of the public good and not from selfish motives. In this connection may we say that we felt very keenly again this year that both the legislators and the public frequently confuse the relationship that exists between the medical profession and the Department of Education, and the medical profession and the Department of Health. When amendments to the Education Law are considered, as, for instance, chiropractic and osteopathy bills, the Department of Education is accused of being too friendly with the medical profession. A telegram received by a legislator demonstrates very concretely the confusion that exists in the minds of some taxpayers as to the relationship of the Department of Health to the Medical Society. This telegram asked the legislator to vote against the "doctors' bill which would create health clinics in all of the counties." It went on to say that the doctors were doing this to create jobs for themselves at the expense of the taxpayers and that the taxes are already too high. The legislator was at a loss to know to what bill the telegram referred. Some confusion is unavoidable and some people will always be confused, however clearly matters may be stated, but here is a condition to which all of us should give some consideration.

J. S. LAWRENCE.

ON TO NEW ORLEANS

President Johnson has appointed Drs. John A. Card, of Poughkeepsie, and Arthur W. Booth, of Elmira, a Transportation Committee for the American Medical Association meeting in New Orleans, beginning May 9, 1932.

The Committee has arranged for the New York delegation to leave New York on the Pennsylvania Railroad, Saturday, May 7, 1932 at

8:10 A. M., Eastern Standard Time, arriving in New Orleans, Sunday evening.

Several Pullman cars have been placed at the disposal of the Committee and tentative reservations for drawing rooms, compartments, or berths may be made by applying to Dr. John A. Card, Poughkeepsie, N. Y.

JOINT COMMITTEE ON GOVERNOR'S HEALTH COMMISSION

A joint meeting of the Committee on Public Relations, and on Public Health and Medical Education was held in the Hotel Roosevelt, New York City, on Wednesday, March 23, 1932, for the purpose of continuing the discussion of problems connected with its report on the Governor's Health Commission. There were present:—Drs. Thomas P. Farmer, Martin B. Tinker, Edward G. Whipple, William A. Groat, Leo F. Schiff, Clayton W. Greene, James E. Sadlier, George M. Fisher, O. W. H. Mitchell, A. J. Hambrook, William H. Ross; and also Drs. W. B. Johnson, J. S. Lawrence and Harry Aranow.

The Committee first considered the subject of State aid to local public health projects, as it had been directed by a vote of the House of Delegates at its special meeting on January 14, for the purpose of making a report at the regular meeting of the House of Delegates on May 23. (See this Journal, February 15, 1932, page 225). After a lengthy discussion the following resolution was adopted:

Resolved, That the time available for the committee to study this subject is too short to make a complete study of the material bearing on the subject.

The committee then took up the consideration of the proposed amendments to the Sanitary Code of the state relating to the qualifications of health officers, especially those of counties as announced in *Health News* of February 8. The following resolution was adopted:

Resolved, That the committee go on record as opposing any regulations that are in opposition to the report submitted by the Joint Committee to the House of Delegates.

It was announced that the Public Health Council would hold a hearing on this amendment prior to its taking effect, and the committee recommended that inasmuch as this regulation is directly related to public health activities, the Public Health Committee should be represented at the hearing by Drs. Farmer, Greene and Whipple. (See page 406.)

(The Public Health Council has announced in *Health News* of March 28, that the hearing will be held on Wednesday, April 13, at 10 A.M., in the offices of the State Department of Health, Room 546, State Office Building, 155 Worth Street, New York City.)

JOSEPH S. LAWRENCE
Secretary of the Joint Committee.

BRONX COUNTY

A regular meeting of the Bronx County Medical Society, held at Elsmere Hall on March 16, 1932, was called to order at 8:40 P.M., the President, Dr. Irving Smiley, in the Chair.

The following physicians were elected to membership: Drs. Max Beiser, James F. Brown, Maurice A. Egan, I. Janeway Ehlin, Morris Harry Hadler, Philip Jaeger, Mandel Jaffin, Charles M. Kapp, Pauline P. Matusow, Adolph Posner and Abraham Seltzer.

Dr. Harry Aranow, Chairman of the State Legislative Committee on Legislation, reported that the Medical Society of the State of New York had succeeded in defeating every bill antagonistic to the medical profession introduced in the session of the State Legislature recently adjourned. He concluded the report by moving that the society express its appreciation to the Bronx members of the State Legislature for their cooperation with the medical profession. This motion was carried.

The President referred to the report of Mr. Howard S. Cullman, Chairman of the Governor's Committee on Compensation Insurance, opposing the free choice of physicians by patients, which

has been answered by Dr. Rosenthal, of New York County.

A meeting was called by Dr. Smiley of representatives of the New York, Kings, and Bronx County Societies, at which the majority and the minority reports were considered. A subcommittee, consisting of Dr. Rosenthal, of New York County, Dr. Projector, of the Bronx, and Dr. McGoldrick, of Kings County, was appointed to make a detailed study of both of these reports and devise a definite plan of action, which will be presented before the annual meeting of the State Society in May. It is our intention to try to prevent such libel of the medical profession in the future.

The scientific program then proceeded as follows:

- Symposium on therapy in thyrotoxicosis:
- Surgical Aspects of Thyrotoxicosis, George W. Crile;
 - The Radiation Results in Toxic Goiter, George E. Pfahler;
 - Discussion, Edward R. Cunniffe and Solomon Ginsburg.

I. J. LANDSMAN, M.D., *Secretary.*

DUTCHESS-PUTNAM COUNTIES

A regular meeting of the Dutchess-Putnam Medical Society was held at Vassar Brothers Hospital March 9, 1932, and was called to order by the President, Dr. William L. Krieger, at 8.45 p.m.

Michael Osnato, M.D., Director Neurology, Post-Graduate Hospital, New York, gave a paper on "Fundamental Conceptions Underlying Neurological Diagnosis."

Drs. G. A. H. Price and C. E. Bauer, of Poughkeepsie, were elected to membership.

Dr. George L. Warner was accepted by transfer from Oneida County.

The following report of the cancer committee was submitted:

"At a meeting of the Cancer Committee, held March 5, 1932, it was decided to make the following recommendations:

"I. That a campaign of education in regard to cancer be carried on in Dutchess and Putnam counties.

"II. That an authority on cancer be requested to address a meeting of this Society in the near future in order that the physicians of this district may become acquainted with the latest developments in the cancer question and may also learn what is being accomplished in other communities in regard to education and methods of prevention.

"III. That organizations throughout Dutchess

and Putnam counties be requested to have a physician from this Society speak on the subject of cancer at a regular meeting. Your committee believes that these talks should be brief, lasting from ten to fifteen minutes and special emphasis should be placed on the precancerous lesions. It also believes that it is important to regard this subject from an optimistic point of view to prevent undue fear or hysteria among the laity.

"IV. That public health organizations and public health nurses be asked to cooperate with us in the educational campaign.

"Helen L. Palliser, Chairman,
James E. Sadlier,
Josiah Coborn."

The report was adopted and the Cancer Committee was empowered to arrange the meetings suggested.

The meeting adjourned at 10.15 p.m. for refreshments.

Attendance 38, as follows:

Drs. Mackenzie, Thomson, Tabor, Christensen, Appel, Voorhees, Breed, Ashley, Poucher, Cadwell, Krieger, Rogers, Marks, Richie, Miller, Baldwin, Lange, Palliser, Stoller, Sobel, Malven, Storrs, Simon, Steblin, Smith, Sadlier, Cotter, Harrington, Rosenthal, Davison, Deyo, Gosse, Stibbs, Whitbeck, Carpenter and three internes.

H. P. CARPENTER, *Secretary*.

LIVINGSTON COUNTY

The annual meeting of the Livingston County Medical Society was held at the White Horse Tavern on Thursday evening, February 25, 1932, jointly with the Livingston County Bar Association.

A short business meeting of the medical society was called at 6:15 p.m. Dr. Edward Smith of Retsof, the retiring secretary and treasurer, furnished the financial report ending December 17, 1931. A formal vote of thanks was given to Dr. Smith for his efficient work.

Officers for the ensuing year are as follows:

President: Dr. R. J. Maichle, Dansville, N. Y.

Vice-President: Dr. G. E. Murphy, Mt. Morris, N. Y.

Secretary-Treasurer: Dr. G. M. Doolittle, Son-yea, N. Y.

Committee on Medical Economics: Dr. F. V. Foster, Caledonia, N. Y.

Committee on Medical Relations: Dr. C. I. Newton, Genesee, N. Y.

Delegate to the House of Delegates: Dr. Tracy Swan, Livonia, N. Y.

Alternate to the House of Delegates: Dr. W. T. Shanahan, Son-yea, N. Y.

Censors: Drs. Preston, Burt, Newton, Shanahan, and Lauderdale.

Dr. F. J. Bowen of Mount Morris, introduced a resolution that the Livingston County Medical Society endorse Mount Morris as a site for the State Tuberculosis Hospital for the seven surrounding counties. This motion was carried.

At 7:15 p.m. the joint meeting repaired to a chicken dinner. Music and singing were enjoyed during the meal.

Dr. Floyd S. Winslow of Rochester presented the paper of the evening with stereopticon views of medico-legal aspects of cases.

GEORGE M. DOOLITTLE, *Secretary*.

WESTCHESTER COUNTY

At the regular annual meeting of the Medical Society of the County of Westchester, held November 17th, 1931, at the Burke Foundation, White Plains, the following officers were elected for the year 1931-32:

President: Dr. Louis V. Waldron, Yonkers;
Vice-President: Dr. Mortimer W. Raynor, White Plains;
Second Vice-President: Dr. A. A. Eggston, Mount Vernon;
Secretary: Dr. Arthur F. Heyl, New Rochelle;
Treasurer: Dr. Harry Klapper, White Plains;
Censors (two years): Dr. Louis B. Chapman, New Rochelle, Dr. C. I. Chapman, Mt. Kisco;
Delegates (two years): Dr. Harrison Betts, Yonkers, Dr. M. E. Marsland, Mamaroneck;
Alternate Delegates: Dr. R. A. Higgons, Portchester, Dr. E. H. Restin, Mount Vernon, Dr. Berton Lattin, Scarsdale.

The following were elected to active membership:

Dr. Frances E. Barnhart, Valhalla
Dr. David A. Laveson, Yonkers
Dr. Ward H. Cook, Yonkers
Dr. H. W. Nottley, White Plains
Dr. Virginia N. Palmer, Scarsdale
Dr. Patrick C. Rizzo, Mount Vernon
Dr. Dorothy M. Lang, Elmsford
Dr. George A. Bullwinkle, Rye
Dr. Edward A. Lane, White Plains

Two very instructive papers on Thyroid Disease were given, one by Dr. Frank Lahey of Boston, on its surgical aspects, and one by Dr. Hurx-

thal, the Associate of Dr. Lahey, on the medical aspects.

Dr. Louis B. Chapman, the retiring President, gave an address, of which the following is an abstract:

The subject of medical economics is of supreme importance to the medical profession at this time. We are on the threshold of changes in the practice of medicine and must prepare ourselves to meet the demands of the people for medical service for all persons. The rich can always purchase it, and the poor have it given to them; but those of moderate means are often impoverished by sickness. Since the distribution of sickness is extremely unequal among families, so also is the distribution of the cost of medical service. The time has come for us doctors to meet the situation, to recognize our own shortcomings and to make a start to correct them. The "middle rate" plan at the Massachusetts General Hospital, Boston, and a somewhat similar plan at Mount Sinai Hospital, New York, are among the evidences that some doctors are trying to solve the problem. If socialized medicine comes, it will be because the medical profession had missed its opportunity to conform to present day conditions.

The Westchester County Medical Society, one of the oldest in the United States, naturally aspires to be a pioneer in medical progress. We look forward specifically to a permanent home, centrally located, with a full-time office staff; to more frequent meetings; to the publication of a bulletin; to the development of a library; and to educational publicity.

ARTHUR F. HEYL, *Secretary*

The regular January meeting of the Medical Society of the County of Westchester was held on the 19th of January, 1932, at the Mount Vernon Hospital. Dr. Russell L. Cecil of New York addressed the Society on the Diagnosis and Treatment of Pneumonia. The discussion was opened by Drs. C. C. Guion and M. D. Touart.

The following were elected to membership:

Dr. S. Franklin Adams, White Plains
Dr. Raymond K. Bush, Mount Vernon
Dr. Leo V. Feichtner, Croton-on-Hudson
Dr. Bernard C. Hecht, Valhalla
Dr. John R. Jeppson, New Rochelle
Dr. Frederick Haskell McKee, Larchmont

Dr. Francis Murphy, Larchmont
Dr. John M. Nicklas, Valhalla
Dr. Stanford Pulrang, Yonkers
Dr. Paul K. Shirk, Yonkers
Dr. Paul A. Ulrich, Larchmont
Dr. Joseph Guard Welling, New Rochelle
Dr. Walter James Wellington, Mamaroneck
Dr. Waring Willis, Bronxville

Dr. Louis B. Chapman submitted a motion to alter the By-laws omitting the Milk Commission and creating a Committee on Economics. This was seconded by Dr. Roberto and was laid over for a vote at the next regular meeting.

ARTHUR F. HEYL, *Secretary*

THE DAILY PRESS

Mr and Mrs—

The Preliminaries to a Public Snooze

From New York Herald Tribune of January 27 1932

COSMETIC PSYCHOLOGY

Why people buy cosmetics in ever increasing amounts in spite of the condemnation of doctors and informers, is told in the following editorial in the *New York Times* of February 20

"What most critics of cosmetics and the absurd claims made for them overlook is the psychological effect they have. If a woman goes to a party with her face clean but unadorned, she spends a miserable, self-conscious evening. But if she strokes it with cream, rubs it with

lotion, lifts it with massage, pats it with powder and applies a ruby flush in a way that pleases her, she will have the consciousness, more consoling than religion, of looking her best. She may have gone in debt to get the permanent wave, the anti-fat remedy may be ruining her digestion, and the total effect of her appearance may be startling rather than beautiful, but she is satisfied. To her it is all worth the money.

COSMETIC CLINICS

Since the makers of school textbooks on hygiene make direct appeals to beauty and happiness as incentives to care for health the 'cosmetologists' seem to be justified in suggesting beauty clinics, as described in the *New York Times* of March 16

"The morale of the woman who cannot have a 'permanent' or have her cosmetic needs attended to became a question of first importance yesterday at the opening of the International Beauty Shop Owners' convention and exhibition at the Hotel Pennsylvania

'Local 14 of the National Hairdressers and Cosmetologists Association voted to organize in the metropolitan area beauty clinics, where proof that the person cannot afford beauty care will insure free treatment

"A resolution to this effect was read

"Whereas the results of a prolonged financial catastrophe of any type or variety manifests itself in a breakdown in the morale of womankind, and

'Whereas the present emergency is following previous trends in this direction and thousands upon thousands of young, beautiful, healthy girls and women are permitting themselves to relapse into a state of mental lethargy which not even the emergence from present conditions will correct, and

"Whereas the relations between the profession of beauty culture and beauty is identically that of the relation between the medical profession and health, the problem of maintaining the morale of women is one which no beauty culturist can avoid since a woman feels as she looks,

"Therefore, with the combined resources of all the associations in the metropolitan area there will be organized beauty clinics where any woman or girl, upon proof of her being unable to afford beauty care, shall receive the best of treatment at no cost"

Physicians will watch the experiment with considerable curiosity

DESSERTS IN DIETS

Adults are only grown-up children so far as eating habits are concerned. If you were turned loose in a restaurant to eat all you want of anything on the menu, what foods would you chose? The New York *Herald Tribune* of February 29th discusses that question in a scientific way in the following editorial:

"So far as eating is concerned, the American people's greatest of suppressed desires in recent times has been apparently in the direction of desserts. A nation-wide survey of gastronomic tendencies on the part of a great restaurant chain, which for the last year has been experimenting with the "all you can eat" for a fixed-price plan, has revealed that, freed from the inhibitions deriving from the check total, what diners wanted most is more and

bigger portions of sweets. Repeat orders where unlimited choice and quantity have been the rule have not substantially increased the consumption of roasts, entrees or vegetables, but have centered in the stage of the meal characterized by apple pie à la mode, peach shortcake, jelly rolls and the more imaginative patisseries.

"Whether or not this circumstance will make for increases in the national waistline and the incorporation of instruction for pastry chefs in the offerings of correspondence schools is problematical, but it is at least indicative of an increased taste for the fanciful and romantic on the part of the public. The realism of roasts is in abeyance, while a nation of public diners indulges in flights of fancy in the realms of exotic sweets."

REPORT OF THE GRIEVANCE COMMITTEE

The report on the work of the Grievance Committee in enforcing the Medical Practice Act during five years, published in this Journal of March 15, page 334, received favorable editorial notice in several Metropolitan dailies. A typical editorial is that in the New York *Herald Tribune* of March 17, as follows:

"Medical quackery in this state has much abated in the five years' diligent enforcement of the Webb-Loomis law strengthening the medical practice act. Many charlatans have been weeded out and the unauthorized use of the title 'Dr.' is practically at an end. Trusting patients are better protected against fakers than they were formerly.

"Thus, the public has benefited. With respect to physicians also, the law has worked with exemplary fairness. When it was in debate some feared that the grievance committee feature might be an instrument of a harassing sort. Composed of ten physicians appointed

by the Board of Regents and serving without pay, the committee has wide disciplinary power; but this authority it has used most equitably, according to the report of Dr. Harold Rypins, secretary of the State Board of Medical Examiners.

"In the five years of its operation the grievance committee has investigated 2,932 complaints of illegal practice. It found 1,866 law violations, of which 1,355 were stopped without criminal prosecution. Cases prosecuted numbered 274, with 205 convictions, nineteen acquittals, forty-three cases withdrawn and seven still pending.

The grievance committee, in fact, is a protection to the physician against whom unjustified complaints are lodged, as well as an effective agent for driving out black sheep. Both for the medical profession and the people of the state the Webb-Loomis law is proving salutary."

THE STUTTERING ACTOR

The stutterer is funny to everybody else than himself. The radios have capitalized this frailty or defect, to the amusement of their audiences, but with unfortunate results which are described in the following editorial in the New York *Times* of February 26:

"One of their difficulties is that some of the most innocent-seeming comedy in the world as they plan it can turn into something objectionable while they have their backs turned for a moment. Lately there have been some stuttering comedians who have become very popular. Perhaps they were inspired by the old

song about K-K-K-Katy and kitchen door. At any rate, radio and talkie audiences took the new art to their hearts.

"Now complaints are beginning to come in. The officials were amazed at first. What could there be in these jolly, stuttering songs to object to? Children especially are delighted with them. It seems that this is the trouble. The children like them so well that they are imitating them and their parents and teachers are not amused. These comedians are now going to be compelled to find some other way of being funny."

BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits or in the interests of our readers.

BOOK REVIEWS

A COMPENDIUM OF THE STATUTE LAW OF CORONERS AND MEDICAL EXAMINERS IN THE UNITED STATES. By GEORGE H. WEINMANN. Octavo of 240 pages. Washington, The National Research Council, 1931. Paper, \$3.00. [Forms Bulletin of the National Research Council No. 83.]

In reviewing this publication we find that for the most part coroners are elected officers although Justices of Peace may function as coroners. The medical examiners which in our opinion handle the work more satisfactorily are only found in the States of Maine, Massachusetts, New Hampshire, New Jersey, Rhode Island and New York City. Coroners, in most instances have no special qualifications and in some states only must they be physicians. There is no uniformity as to qualifications. In our opinion, the lamentable feature of the entire system throughout the states is the lack of uniformity as to qualifications of personnel and regulations governing them.

Inquests can, in most cases, be most advantageously conducted by a regular convened Grand Jury of the county in which the alleged crime is committed because for the most part, this inquest is but a preliminary hearing or investigation as to the cause of death.

Under the heading of autopsy most laws require that it shall be performed when the cause of death cannot otherwise be determined. This, of course, is totally inadequate in as much as an autopsy properly performed should determine all information that may be necessary for the proper prosecution of the case. This particular research may take one far beyond the cause of death and yet the information gained would be absolutely essential for the proper administration of justice.

The recommendations in the final paragraph of the introduction of this "Bulletin" well summarize what is most desirable, the medical examiner or coroner should be a person skilled in the science of medicine and pathology and that the law should be completely codified and made uniform throughout the nation if practicable, guaranteeing to the people of the community, no matter how sparsely settled, all the benefits of modern scientific knowledge and experience.

M. MARTEN.

SCHOOL VENTILATION Principles and Practices. Final Contribution of the New York Commission on Ventilation. By C.-E. A. WINSLOW, Chairman, and others. 12mo of 73 pages. New York City, Columbia University Teachers College, 1931. Cloth, \$1.00.

This book gives a concise history of the progress of proper ventilation with especial reference to schools. It reviews the hygienic relationship and effects of ventilation.

It reviews the previous attempts and now gives the final work on proper ventilation principles as laid down by the New York Commission on Ventilation.

Sanitary engineers would do well to study this survey.

J. J. WITTMER.

A DESCRIPTION OF THE PLANES OF FASCIA OF THE HUMAN BODY with Special Reference to the Fascia of the Abdomen, Pelvis and Perineum. By B. B. GALLAUDET. 12mo of 75 pages, illustrated. New York, Columbia University Press, 1931. Paper, \$2.00.

This small descriptive booklet, containing 59 pages of text and 6 figures drawn by the author, represents actual dissections by him on 34 adult human bodies.

Dr. Gallaudet has certainly most accurately and briefly described the fascial planes of the abdomen,

pelvis and perineum and has done exceedingly well in his attempt to prove the law of continuity of fascial planes in the body.

He should be commended for this work on a section of anatomy which has undoubtedly been inadequately described in the average textbook.

HERBERT T. WIKLE.

MIDWIFERY FOR NURSES. By DOUGLAS MILLER, M.D., F.R.C.S. 12mo of 256 pages, illustrated. London, Edward Arnold & Company; New York, Longmans, Green & Company, 1931. Cloth, \$2.40.

The author has written this volume to supplement the practical instruction in midwifery which the nurse receives in the hospital. The book is divided into nine parts, and covers the subject of Anatomy and Physiology, Physiology of Pregnancy, Management of Pregnancy, Normal Labor, Pathology of Pregnancy, Abnormal Labor, Pathology of Puerperium, The Infant, and Obstetrical Operation, and Anesthesia.

The text is clearly written in simple language and contains only such data of which a nurse should have knowledge.

The volume is excellent as a textbook of midwifery for nurses.

W. S. S.

ON THE EDGE OF THE PRIMEVAL FOREST. Experiences and Observations of a Doctor in Equatorial Africa. By ALBERT SCHWEITZER, Dr. Med. Translated by C. T. CAMPION, M.A. 12mo of 180 pages, illustrated. New York, The Macmillan Company, 1931. Cloth, \$2.00.

How many doctors would give up their practices, however small, and their families out of sympathy for the physical miseries of the African natives? Doctor Schweitzer, a doctor of theology as well as of medicine, gave up a university professorship, a comfortable home, and artistic background in order to become a medical missionary. It was a religious zeal rather than scientific curiosity which prompted him to venture on such an unusual undertaking; or, to use his words—"the sympathy which Jesus and religion generally call for." However different his motives may have been from those of the strict practitioner of medicine the fact remains that in his own way he found the opportunity of doing much good.

EMANUEL KRIMSKY.

HEALTH FOR TRAVELERS. Hygiene and Health Preservation in the Tropics, Orient, and Abroad. By the Staff of the Pacific Institute of Tropical Medicine Within the George Williams Hooper Foundation for Medical Research of the University of California. Edited by ALFRED C. REED, M.D. 12mo of 239 pages. San Francisco, J. W. Stacy, Inc., 1931. Cloth, \$3.00.

This new handbook is written especially for those contemplating travels to the tropics. We are first introduced to the variations in temperature and in humidity that one may expect with changes in latitude as well as altitude. Simple and comprehensive directions are given concerning the common dangers to be avoided. There are some facts here and there that will interest the medical man. For example, we are told that "many persons (about 50%) who die of snake-bite really die of fright or from the treatment." There are directions on sterilizing water with iodine and sodium hyposulphite successively where boiling is impossible. Dried milks are used extensively in the tropics for adults as well as children. This book should prove a thoroughly reliable and friendly guide for the traveler.

EMANUEL KRIMSKY.

GYNCOLOGY AND UROLOGY FOR NURSES By SAMUEL S. ROSENFELD M.D. F.A.C.S. 12mo of 230 pages illustrated New York: William Wood and Company, 1931. Cloth \$2.00.

A small textbook in which the student nurse may find gynecology and urology in one volume. A new departure. The subject matter is good well arranged and practical. Illustrations showing nursing technique are excellent but the pictures of pathological specimens and operative procedures might well have been omitted. C. A. G.

THE COMMONER NERVOUS DISEASES FOR GENERAL PRACTITIONERS AND STUDENTS By FREDERICK J. NATTRASS M.D. F.R.C.P. Octavo of 218 pages illustrated New York: Oxford University Press, 1931. Cloth \$4.00 (Oxford Medical Publications).

The book is based upon the experience of post graduate teaching of neurology given to general medical practitioners. More emphasis is placed upon the different clinical manifestations of the various neurological diseases than upon anatomical and physiological considerations. It emphasizes the salient points of each disorder with discussion of the various different manifestations of each condition. Twenty chapters are devoted to the elucidation of the commoner neurological conditions. Inflammatory and degenerative and neoplastic diseases are given thorough consideration. Traumatic disorders are not discussed. As a whole the book is admirably presented and satisfies the purpose for which it is written, i.e. a discussion of the common neurological disorders before a group of medical practitioners with the chief objective of recognizing these disorders and of instituting adequate therapy. IRVING J. SANDS.

SIMPLIFIED DIABETIC MANAGEMENT By JOSEPH T. BEARDWOOD JR. A.B. M.D. and HERBERT T. KELLY M.D. A.A.C.P. 12mo of 191 pages illustrated Philadelphia: J. B. Lippincott Company [c1931]. Cloth \$1.50.

The book is divided into three chapters the first containing the essentials that every diabetic patient should know, the second more advanced information of interest to patient and physician and the third various food values, recipes and menus. The principal difference from other similar books is the recommended use of a plan called the unit method which the authors think simplifies diabetic management.

Three units are used—Group A in which each food listed is equivalent to 5 grams of carbohydrate, 1 gram of protein and yields 24 calories. Group B 5 grams of protein, 10 grams fat, 110 calories and Group C which represents in each unit 5 grams of carbohydrate, 6 grams of protein and 10 grams of fat yielding 134 calories. Each unit of Group C represents one unit of Group A and one unit of Group B.

Nineteen diets have been calculated with the unit method charts. Diseases other than diabetes or complicating it as nephritis, cardiac decompensation, epilepsy and obesity may be treated by the application of the method. There is a chapter containing the content in the salts (sodium chloride and sodium bicarbonate) of various foods as compiled by Dr. F. M. Allen with whose ideas about salt the authors apparently agree. W. E. McCOLLON.

THE FOUNDATIONS OF MEDICAL HISTORY By SIR D'ARCY POWER K.B.E. F.R.C.S. 12mo of 182 pages illustrated Baltimore: Williams & Wilkins, 1931. Cloth \$3.00 (Johns Hopkins University Institute of the History of Medicine).

This is an octavo of 180 pages and 3 illustrative plates

which properly belongs on the Doctor's bookshelf. It is written in a chatty, pleasing style and bears abundant evidence of the Author's thorough knowledge of his subject. It is compelling in a direct invitation to the doctor of literary taste to try his hand at iconographic work. Furthermore it is replete with methods of accomplishing such a task—a fact which particularly recommends it to beginners. Sir D'Arcy Power's book comprises a series of six lectures delivered at the Institute of the History of Medicine of the Johns Hopkins University with an introduction by Dr. William H. Welch who characterizes the Author as a distinguished and charming personality whose visit to Baltimore has left delightful and enduring memories. J. M. VAN COTT.

CANCER AND RACE. A Study of the Incidence of Cancer Among Jews Conducted under the Auspices of the Jewish Health Organization of Great Britain. By MAURICE SORSBY M.D. F.R.C.S. Octavo of 120 pages. New York: William Wood and Company, 1931. Cloth \$3.00.

Dr. Sorsby has ambitiously undertaken the burdensome task of collecting statistics on the incidence of cancer in Jews as a race and of the frequency of that disease in both orthodox and reformed Jews respectively. Unfortunately however these studies will not lend the author or the reader to trace even a distant etiological basis for cancer. In fact if Shylock were to plead his cause at the present time he might use just such a book as convincing evidence of the equal susceptibilities of the Jew and Gentile to this disease. EMANUEL KRIVSKY.

INFECTIONS OF THE KIDNEYS By FREDERICK F. CAMPBELL M.D. F.A.C.S. 12mo of 343 pages illustrated New York: Harper & Brothers, 1931. Cloth \$3.00 (Harper's Medical Monographs).

The book is one of Harper's Medical Monographs. It is written for the medical practitioner who should welcome it for its conciseness, its completeness and its modernity. The author has taken great pains in collecting all the new findings pertaining to kidney infections and presents them with his judicious comment which appears to be very sound.

The chapter on kidney infections in childhood will be of interest to the urologist.

The illustrations are schematic but serve their purpose very well; there is a table of contents and a good index. H. L. WEHRBEIN.

SURGICAL PATHOLOGY OF PROSTATIC OBSTRUCTIONS By ALEXANDER RANDALL M.A. M.D. Quarto of 267 pages illustrated Baltimore: Williams & Wilkins, 1931. Cloth \$7.00.

This work is based upon autopsy findings noted in 1218 specimens of the bladder and prostate. In this group there were 312 instances of gross pathological change in the prostate. There is presented a clear and concise correlation of all the pathological and clinical data which have been demonstrated as a result of this very long and painstaking investigation. There are a large number of excellent illustrations taken from actual photographs and accompanied by brief clinical histories of the cases under discussion.

Through the medium of numerous papers presented from time to time by Dr. Randall the profession has been made familiar with his work. The presentation of all of this work with 15 findings and conclusions in a single volume is a distinct contribution to medical literature. The book should find a place in the library of every urologist. N. P. RATHBUN.

OUR NEIGHBORS

MEDICAL SOCIETY AND PUBLIC HEALTH IN ALABAMA

The January number of the Journal of the Medical Association of the State of Alabama comments editorially on the legal responsibility of Alabama doctors in public health through their State organization:

"In states other than Alabama, the practicing physician aligns himself with organized medicine largely because of ethical considerations and because of the personal advantages which accrue from such affiliation. Membership in other state medical associations or societies carries with it no clean-cut, legal responsibilities to the citizens of such states; the obligations and purposes of such societies find expression in the promotion of scientific medicine and of the general welfare of their members as related to the board scheme of modern day social organization. This, in no sense, means that the humane, philanthropic attitude, which should characterize every earnest physician, is discouraged; but it does mean that no definite, legal obligation attaches to such membership. History abundantly points out that a fixed responsibility serves as a potent lever in productivity; and human nature is such that, in the absence of such responsibility, output lags, consequently there is a direct ratio existing between productivity and responsibility.

"In Alabama's scheme of organization, the legislature has definitely placed upon the organized profession the direction and control of all public health affairs within the State. The County Medical Societies, speaking through their respective Boards of Censors, become the County Boards of Health; and the State Medical Association, voicing itself through the State Board of

Censors and its State Health Officer becomes the State Board of Health. It is because of this responsibility and the courageous manner in which organized medicine has met these obligations, that much of our success in this field of endeavor is due. Sane leadership we unquestionably have had; but leadership alone, without the mighty and articulate backing of a unified, interested medical profession, would never have produced such happy results. The public health worker cannot advance far beyond the vision or scope of the crystallized medical thought existing in any community without immediately encountering difficulty. One of the marvels revealed to visitors from other states and other countries when coming in Alabama, is the splendid type of cooperation given to health workers by the entire profession; and yet to the doctors of this state this does not seem strange, because of the fact that they recognize and assume their own responsibility in this important regard. The new and younger acquisitions to our profession should quickly acquaint themselves with the details which make them a vital part of the health machinery of this state. Regular attendance upon the meetings of the County Medical Society; a familiarity with the various activities conducted by the health workers within a county and a careful study of the constitution of the Association and the health laws of the state offer ready means for giving this necessary information.

"With this information once acquired, and the proper vision caught, the practicing physician in Alabama becomes not alone a healer of the sick; he becomes much more; he becomes a promoter of health and a preventer of disease."

PUBLIC HEALTH ADMINISTRATION IN ALABAMA

The State Board of Health of Alabama is the Medical Association of the State. The February number of the Journal of the State Association contains an article by Dr. J. N. Baker, State Health Officer, which says:

"The State Health Officer wishes very much that a copy of a recent publication by the Commonwealth Fund entitled, 'Child Health and the Community' by Courtenay Dinwiddie, might be placed in the hands of every physician practicing in this State. A few excerpts from this little book are given below, which admirably serve to show the attitude of the officials of this Fund towards the practicing profession, and also how necessary it is for any

forward-looking health program to have the undivided and sympathetic support of the profession.

"In Alabama, because of the interest, responsibility and voice given by law to organized medicine in the direction and control of public health affairs, it is felt that less friction and misunderstanding creeps into the relation of these groups than likely occurs in any other state. The present State Health Officer, who for many years trod the same path which every active physician is now treading, would like to feel that he has the confidence of the entire profession whose interests and welfare he

shall ever strive to most zealously guard, in the effort to solve the many problems now confronting both the profession and health workers."

The article quotes the following principles set forth in the book:

"1. The public interest must be paramount. This is a general statement to which almost any one will agree until the ideas of others as to the public interest come into conflict with his own ideas as to his private interests.

"2. The interest of any group that is contributing to the solution of a public problem must to that extent be considered a public interest.

"3. Physicians constitute a body of citizens whose training has prepared them to render a service to public health for which there is no adequate substitute.

"4. Physicians in private practice perform a service in the treatment of disease, whether as individuals or in fully organized groups, whether in private offices, clinics, hospitals, or homes, that is the accepted mode of treatment, in this country, for those able to pay for such service.

"5. Physicians in private practice, because

of their training, numbers and relationships to their clientele, constitute the one group which is potentially most capable of applying the lessons of preventive medicine to the habits and circumstances of the individual. They are largely unprepared to render such service because their training and experience have been chiefly therapeutic.

"6. The public is largely unready to demand or pay for such guidance in the application of the lessons of preventive medicine to personal problems.

"7. An honest, consistent, and cooperative effort should be made by the organized medical profession, the health authorities, and private groups interested in public health to develop public demand for preventive services by private physicians whether practicing as individuals or in organized groups.

"8. An inseparable corollary to this effort should be the conscientious preparation of physicians for such services, without which the attempt to build up satisfactory preventive services by private practitioners is doomed to failure.

"9. Health conferences or preventive health center medical services conducted by the health

PHENO-COSAN promptly
relieves skin troubles

PHENO-COSAN was primarily formulated for the treatment of eczema. In this condition, clinical reports show consistent success.

In addition, physicians report gratifying results in Tinea, Tinea Phytosis and Impetigo Contagioso.

PHENO-COSAN has a vanishing base and requires no bandages. Contains *no mercury* and is of special value in infant cases.

It is regularly supplied to U. S. Government, State and Civic hospitals.

Whitney Payne Corporation

(Continued from page 426—Adv. xvi)

department, especially for babies and younger children, are justified and desirable (a) as a means of creating a demand for such services, (b) as an agency of inaugurating proper standards for such services, (c) as a practice ground for physicians in the art of preventive medicine, and (d) as a supplement to the preventive services of private practitioners, so long as conscientious efforts to make such service adequate to the public needs have not been successful.

"10. The paramount interest of the public must come to the fore especially in any question of the control of communicable disease. Leaving to the private practitioner as much latitude as possible in all discretionary matters of treatment, the health officer should take responsibility for promoting such immunizations as are accepted as part of the necessary protection of the community, and must assume final authority for all control measures and for diagnosis in so far as that is necessary to insure prompt and accurate recognition of cases."

PUBLIC HEALTH ACTIVITIES IN GEORGIA

The February issue of the Journal of the Medical Association of Georgia contains a review of the public health activities of the Georgia Department of Health written by Dr. T. F. Abercrombie, Director. Those activities of special interest to practicing physicians are described as follows:

"At the present time, there are thirty-eight counties in the state carrying on full-time health programs, including two districts. Approximately fifty per cent of the population is located in these counties having public health service. Economic conditions have made it difficult for many of them to carry on the work; however, health work was discontinued in only one county last year.

"A mobile health unit has put on demonstrations of county health work in eleven counties. The personnel consists of a health officer, nurse, and a sanitary inspector. This unit has demonstrated the value of full-time health work in rural counties.

"Since the typhoid fever problem in Georgia is a serious one, the county health officers of the state have been requested to follow up every case of this disease during convalescence with the view of detecting and eliminating carriers. The problem will be lessened considerably when carriers are controlled.

"During the month of May, through cooperation with the Georgia and Florida Railroad, a health exhibit train was operated over the

A VALUABLE ADJUVANT IN

Bronchitis .. Pleurisy Pneumonia

WITHIN EVERY DOCTOR'S EXPERIENCE there are cases where his skill and good judgment have suggested the external use of mustard. A mustard poultice relieves inflammatory conditions, internal pains and congestions.

Mustard's medicinal value rests in its volatile oils. The warm water which is added to the ground seed activates the enzyme myrosin which liberates the oils from the glucosides. Then follow the valuable, well-known, counter-irritant, stimulant and revulsant effects.

COLMAN'S MUSTARD is grown where natural soil and climate conditions favor the production of the greatest amount of these volatile oils. It is ground and packed in ways to preserve them. So to be sure of the greatest therapeutic effect, specify Colman's each time you prescribe mustard.

Colman's Mustard

Georgia and Florida line. More than 20,000 people viewed the exhibit and attended the lectures given each night.

"The summer roundup of pre-school children was conducted in every county in the state through co-operation with the Parent-Teacher Association. The President of the Medical Association of Georgia appointed a physician in each county to make physical examinations.

"Findings are beginning to show interesting figures as to the distribution of hookworm and other intestinal parasites in the state. Many of the sections of South Georgia still show high incidence of hookworm, while others in the upper half of the state are relatively free of hookworm.

"The technique of culturing throats of all convicts was employed in an outbreak of meningitis in the United States Penitentiary. In this way, the carrier was located in the person of a prisoner who had meningitis six months ago.

"About sixty tons of dried brewers' yeast were distributed during 1931. Aside from many individual testimonials which have reached this office, there is yet no reliable method of determining the value of yeast in

the prevention and treatment of pellagra. Something has lowered the mortality, while neighboring states report increased mortality.

"Diphtheria toxoid and toxin-antitoxin are not being used as much as merits justify in spite of the fact that the price to the consumer has been reduced to forty per cent of the cost price. Of each dollar spent for these products, thirty per cent is paid by the Bankers Health & Life Insurance Company of Macon, thirty per cent by the State Department of Health, and forty per cent by the consumer.

"The laboratories supply the freshly prepared dilutions of tuberculin to health officers and others engaged in the early diagnosis of tuberculosis.

"Extension courses for rural physicians were conducted jointly by the University of Georgia, Emory University, and the State Department of Health at six different points throughout the State. A total of 315 physicians, from 81 counties, attended these courses.

"Beginning August 24th, through co-operation with Emory University, the Children's Bureau, and the Rosenwald Fund, a five-day course was held in Atlanta for the Negro physicians of the State; 53 colored doctors attended this course. The Rosenwald Fund

Overcoming Toxic Absorption by Detoxification

The far-reaching systemic effects of intestinal toxemia are generally appreciated, but the methods offered for its correction have usually proved unsatisfactory.

Opposed to the irrational use of cathartics, so-called intestinal "antiseptics" and trick diets, is the rational approach to the problem offered by Detoxification.

Clinical investigation appears to substantiate the earlier laboratory investigations of Larson, which showed that Soricin—a physiologically standardized preparation of purified sodium ricinoleate—exerts a detoxifying action on the enteric flora.

Soricin Capsules are offered in two sizes: 5-grain and 10-grain. For the administration of the larger doses required at the beginning of treatment, the 10-grain Soricin Capsules are suggested. For the subsequent prolonged treatment, the 5-grain capsules will be found convenient.

Full descriptive literature giving complete outline of treatment will be gladly mailed upon request. THE WM. S. MURRELL COMPANY, CINCINNATI, U. S. A.

CHIROPRACTIC INITIATIVE IN MASSACHUSETTS

The *New England Journal of Medicine* of December 31, 1931, contains the following note on a legal petition of the chiropractors of Massachusetts to the Legislature:

"Although the law requires the signatures of but twenty thousand registered voters on a petition of initiative, the chiropractors recently filed one with the office of the Secretary of State of Massachusetts with sixty thousand signatures. They were obtained as follows in the several counties:

"Barnstable, 248; Berkshire, 1,751; Bristol, 3,741; Essex, 9,200; Franklin, 1,367; Hampden, 4,349; Hampshire, 1,163; Middlesex, 17,800; Plymouth, 4,715; Worcester, 7,150; Suffolk, 7,338; and Norfolk, 1,959.

"The cities and towns were represented as follows:

"Pittsfield, 1,136; New Bedford, 1,800; Taunton, 1,049; Amesbury, 914; Gloucester, 1,007; Lawrence, 1,536; Lynn, 766; Newburyport, 1,400; Orange, 540; Holyoke, 1,706; Springfield, 1,326; Fitchburg, 1,166; Worcester, 3,394; Leominster, 378; Ware, 373; Cambridge, 700; Everett, 1,819; Lowell, 2,753; Marlboro, 2,022; Medford, 700; Melrose, 700; Newton, 700; Somerville, 1,100; Waltham, 1,450; Woburn, 600; Quincy, 1,100; Brockton, 1,900; and Boston, 7,000.

"This survey of the petition will give the general public a very good idea of the intention of the chiropractors to locate in these places. The canvassers undoubtedly obtained many signatures from individuals who will not vote in favor of the petition. It must be admitted that physicians in these several cities could have obtained many more signatures in opposition to a change in the statutes if they so desired.

"We are not dismayed or even depressed by the problem which confronts us. The present requirement of one standard to determine the qualification of fitness to practice the healing art in this state has been attacked.

"The approval of chiropractic methods in Massachusetts now rests with the citizens of this Commonwealth. The medical profession will, as in other public health fields, present the facts. The final decision will be a demonstration of approval or repudiation of scientific medicine.

"If intelligent study can be brought to bear on this subject there will be a satisfactory answer. It is of vital importance that the medical profession should act unanimously, not by reason of selfish interest, but because of its responsibility in leadership in public health education."

PUBLIC RELATIONS IN WYOMING

The February number of *Colorado Medicine* records the action of the President of the Wyoming State Medical Society, D R H Sanders, in appointing a committee of nine members to constitute a committee on Public Policy and Legislation, and says

"It is to this committee that the citizens and officials should turn for advice on all questions of health and disease. Unbiased and a strictly scientific source of information on all questions of public health and medical knowledge, its opinions should and will be the court of last resort

"This committee will serve for a term of years so that its membership will in most cases serve for at least five years. The committee will cooperate with the State Legislature, the Governor, and Board of Charities and Reform, the State Board of Health and all other state boards as well as county and city officials, on all medical and health problems

"With such a committee to consult with, state, county and city officials can no longer plead ignorance or hope to escape just criticism if they act on public health matters without consulting this committee

MEDICAL PUBLICITY IN FLORIDA

The February number of the *Journal of the Florida Medical Association* has the following editorial on medical publicity in the newspapers of Florida

"Newspaper releases and announcements of radio broadcasts have been given to all the newspapers of the state. The press releases have been going out weekly the past nine weeks. In order that the Public Relations Committee may learn of the reception their press releases are receiving all members of our Association are requested to clip the items appearing in their local papers and

forward them to Box 81, Jacksonville. The clipping of these releases and forwarding them to the central office will be of considerable help to the Public Relations Committee as an indication of the value of the task they have undertaken, for it is quite important that reliable information be received regarding the number of papers in the state that have given space to the Committee's press releases"

EDITORIAL THOUGHTS FROM NEBRASKA

The editor of the *Nebraska State Medical Journal* for February comments on the source of articles, as follows

"During the year 1931 there has been an abundance of copy furnished to the editor and it has been somewhat embarrassing at times to decide what or which articles to publish next—they all deserved early publication. At the time this is being written the supply is still adequate to carry us over the annual meeting. We mention this for two reasons that essayists may know that we are doing the best we can to get material published, and to let prospective contributors know that we are always glad to get something real good"

The editor also has his troubles with authors who use much space in saying little

"A correspondent sent us the following criticism months ago about an article published during the past year. We now offer it to the reader. The criticism was specific, but applies to other articles and should be a suggestion to authors. *The Medical Journal*, which came yesterday, had a number of interesting articles. I think the man who wrote the article on— had a good topic but he wasted several pages saying nothing and then it was time for him to give his conclusions. He had no ideas that were new to anybody, to offer. The article on *Trichomonas* was more definite than any of the other articles on the same subject which I had read"

CLASSIFIED ADVERTISEMENTS

Classified ads are payable in advance. To avoid delay in publishing, remit with order. Price for 40 words or less, 1 insertion, \$1.50; three cents each for additional words.

AN OPPORTUNITY TO EARN \$15,000

Mead Johnson & Company announces an award of \$15,000 to be given to the investigator or group of investigators producing the most conclusive research on the Vitamin A requirements of human beings.

Requirements

Candidates for the award must be physicians or biochemists, residents of the United States or Canada who are not in the employ of any commercial house. Manuscripts must be accepted for publication before December 31st, 1934, by a recognized scientific journal. Investigations shall be essentially clinical in nature, although animal experimentation may be employed secondarily.

Committee on Award

The Committee on Award will consist of eminent authorities who are not connected with Mead Johnson & Company, the names of whom will be announced later.

Source of Supplies

There are no restrictions regarding the source of Vitamin A employed in these investigations.

For other details of the Mead Johnson Vitamin A Clinical Research Award, see special announcement, pages 14 and 15, in the *Journal of the A. M. A.*, January 30, 1932. See page xxx.—*Adv.*

BiSoDol

Gastric disturbances caused by overeating and alcohol are usually associated with hyperacidity. Treatment of these ailments consists in neutralizing the excess acid in the digestive tract.

BiSoDol offers quick relief from vomiting and nausea due to hyperacidity because it contains in its formula balanced alkalis—sodium and magnesium bases—with bismuth, digestive ferment, and oil of peppermint.

BiSoDol is palatable and well tolerated by the digestive tract. Its balanced formula decreases the tendency to alkalosis which results from single alkali medication. See page ix.—*Adv.*

COMPULSORY HEALTH INSURANCE ABROAD

By EMIL KOFFLER, MD, NEW YORK, N. Y.

A report of the Special Committee on the Study of Health Insurance of the Bronx County Medical Society given February 17 1932

INTRODUCTION If the present depression has taught us something, it is that the world must be considered as a unit and that there is not such a thing as continental isolation or national self-sufficiency. Economic and social events or changes in one country must necessarily have their repercussion all over the inhabited world and national or geographical boundaries are even less effective in stemming social or economic tides than they are for instance, in checking epidemic disease.

A first hand information of what is going on in other countries—especially in the so called old world so similar in culture and tradition to our own—is therefore necessary if we want to face intelligently and understandingly the problems we will be confronted with sooner or later in our own country. Rather sooner than later, according to my own feeling.

The economic and professional aspects of the practice of medicine are deeply affected and changed abroad and we must take cognizance of every change in order to know what awaits us here.

Mindful of this truth the present splendid administration of our County Medical Society has made an effort to get an unbiased and reliable account of what is happening in this field and has appointed a special committee on the study of Compulsory Health Insurance abroad. Three members of this Committee of four are foreign graduates two have a direct and personal acquaintance with compulsory health insurance practice abroad and have completed their previous experiences by a renewed sojourn in Germany and Austria one year ago.

When I accepted the chairmanship of this Committee I had followed for many years every phase of this question and knew that I would have no difficulty in getting the literature and data of publications in English, German and French. After I took the plunge I found out that the real difficulty was how to get out and bring you a comprehensive and brief exposé of the situation. Out

of about 1,300 references listed we have selected 44 publications which we studied and which constitute the bibliography appended to this article.

Historic Survey The French revolution of 1789 in its formulation of "*les droits des hommes*" was the first to recognize that the organized society has the duty to guarantee to each individual protection and support in case of sickness. However the real precursors of the health insurance movement were the old trades guilds and their mutual protective organizations.

In **GERMANY** the first mutual organization for assistance and sick benefit is represented by the miner's union or *Knappschaftskasse* which numbered 53 funds with a membership of 56,500 people in 1841. This organization has preserved its separate entity up to this day. In 1849 the Prussian Industrial code asked the employers to insure workmen against illness and taxed them with 50% of expenses incurred.

In 1876 there were 12,000 *Hilfskassen* with a membership of 2,000,000 people occupied in industries.

In 1881 Bismarck in following his anti-socialistic policy wanted to put the State on record as the fatherly guardian of the welfare of his working people and so introduced the principle of compulsory health insurance by appropriate legislation.

The act of June 16, 1883 was the first legislative expression of the State asking and sponsoring collective protection against sickness, accidents during work and old-age insurance. To this large group was added gradually unemployment insurance, maternity benefits, pensions for permanent injuries and funeral expenses—all these activities under State control and legislation. This is what constitutes the so-called Social Insurance.

In **GREAT BRITAIN** there were early forms of contract practice in the economically limited industrial and agricultural areas—besides the Poor Law system.

1) Many doctors had their own "private clubs" collecting from their members small weekly con-

tributions in return for which the entire family was attended. These contributions were about 3d. per week.

2) Other doctors arranged with the owners of factories for medical attendance of employees. Deductions were made from the wages of such employees and turned over to the doctor covering thus the medical care of the entire family of each employee.

3) Friendly Societies and Trade Unions. These bodies had branches throughout the country and provided benefits against unemployment, sickness and funeral benefits. Later they provided medical attendance. Each local branch or lodge appointed its own doctor and paid sums from 2s. 6d. to 5s. per member per year, for which ordinary medical care was obtained.

This system was completely analogous to the lodge contract practice in U. S. A. The well-known insufficiencies and abuses prevailed: a) low remuneration of doctors, b) superficial and perfunctory medical service, c) abuse on the part of the client, d) overburdening of doctors on account of large numbers of patients, e) canvassing and all kinds of questionable procedures on the part of the doctor, f) low esteem for this form of medical practice from both sides.

An important step was achieved when Great Britain in its desire to emulate Germany promulgated the *Act of January 1913*.

In the course of time other countries followed suit with similar acts of legislation (as shown in table I).

Table I shows for a number of countries the dates of enactment of laws of compulsory insurance and also the kind of workers affected by these laws.

TABLE I
LAWS INTRODUCING COMPULSORY
SICKNESS INSURANCE

Country	Year of Enactment	Workers Covered
GERMANY	1883.....	Industry
	1885.....	Commerce
	1886.....	Agriculture

Sickness Insurance in Europe
Commission on Medical Education

Table II indicates countries which have compulsory health insurance on their statute books. Some of these have also voluntary health insurance organization.

TABLE II
COUNTRIES HAVING COMPULSORY
SICKNESS INSURANCE

1929	1930
Austria	Belgium
Bulgaria	*Chile (All population)
Czecho-Slovakia	Estonia
France (Alsace-Lorraine)	Germany
Great Britain	Greece
Hungary	Irish Free State
Italy (New Provinces)	Japan
Latvia	Lithuania
Luxemburg	Norway
Poland	*Portugal (All population)
Roumania	Russia
Yugo-Slavia	*Switzerland (All population of 6 cantons)

* Some also have Voluntary sickness insurance.

(Appendix—Sickness Insurance in Europe, Commission on Medical Education)

Table III indicates countries which have mostly a system of voluntary health insurance. Some of these have also compulsory insurance legislation but the former system is prevailing. For instance: Switzerland, a country distinguished by its local autonomy has only 6 cantons out of a total of 22 in which compulsory health insurance obtains.

TABLE III
COUNTRIES HAVING VOLUNTARY
SICKNESS INSURANCE*

Argentina	Australia
Belgium	Canada
Denmark	Finland
France (Compulsory 1930)	Great Britain
Northern Ireland	Italy
Netherlands	New Zealand
Palestine	Spain
Sweden	Switzerland
Union of South Africa	Uruguay

* Some also have Compulsory sickness insurance.

(Appendix—Sickness Insurance in Europe, Commission on Medical Education)

The latest country to enter the column of compulsory health insurance is *FRANCE*, August 1930.

We see therefore an uninterrupted triumphant march of *Socialized medicine* during the last 50 years. We prefer to call this system *Socialized medicine* and not *State medicine* which has other implications. The real *State medicine*, that is practice of medicine as civil servants under supervision of the State obtains only in U S S R. In Russia practice of medicine is a function of the State and doctors are State servants. The State bears the full cost of medical education and the graduates are at the disposal of the State. Fifty per cent of the medical students are women.

Doctors are paid monthly salaries varying from \$60 to \$120. Hospitals, clinics, maternity care, nurseries, treatment of venereal diseases and advice on contraception are free to the population. Beginning January 1, 1932 salaries of medical workers were increased 23% in accordance with a recent decision of the Council of People's Commissars (*Economic Review of the Soviet Union*, January 15, 1932, p. 48).

Organization, Its General Principles. Before presenting along general lines the most essential points in the organization of compulsory health insurance we wish to make a clear distinction between this kind of insurance and any other system of voluntary insurance.

In compulsory insurance there are three parties to the insurance contract: 1) the State representing organized Society, 2) the insurance carrier, the insured. The State by its inherent power of legislation makes the insurance *mandatory* on employers and employees alike, supervises the fulfillment of the provisions of the contract and makes the transaction independent of economic returns by subsidizing the undertaking with means obtained by direct or indirect taxation of its entire population. Social insurance is never paying its own way except in prevention of suffering and of social unrest.

In some countries like Denmark and The Netherlands the State supplements voluntary insurance by subsidies, free hospitalization and by benefits derived from the old poor law system.

This system also differs from compulsory insurance in so far as it does not make insurance *mandatory* on every enterprise employing wage earners. Compulsory insurance on the other hand does not consider whether an enterprise is profitable or not but aims to distribute the cost of its maintenance over the whole range of productive activity.

It is therefore more social as it does not burden only the economically sound enterprise which insures its workmen voluntarily but also applies to the workers in weak industries which can not afford insurance and are at the same time mostly in want of support.

In compulsory health insurance the following points must be considered:

Principles. Distributing the economic burden of medical care over a large fraction of the population.

Financing. Combination of contributions from the insured persons' employers, compulsory savings and indirect taxation.

Tendency. Fractional programs to include insurance against incapacity, disablement, unemployment, old age and other economic risks.

Further tendency. Shift from 'cash benefits' to "benefits in kind" (Irish Free State).

"Benefits in kind" include medical treatment, drugs and optionally additional benefits as hospital, dental, ophthalmic and sanatorium treatment.

Restoration rather than compensation is the principal function of present day insurance.

Sickness Insurance tends to be put on a basis of family insurance.

Grouping—by trade (earliest) (Part of trade union or group or local) by territorial capitation.

Insurance carriers and is based on the contract of employment.

Voluntary contributors admitted.

Of 23 countries where compulsory health insurance obtains 20 are restricted to wage earners.

In Table IV we have taken for comparison 3 countries representing to our mind 3 differentiated types: Germany—the first country with social insurance for the last 50 years, Great Britain—on account of its similarity in culture, language, etc. to our own country, and finally Austria or rather autonomous Vienna which is the most advanced along lines of socialization. All the other countries have pretty uniform features with some differences of detail.

Under the common denomination of "funds" we understand the different insurance carriers.

They are in Great Britain the previous friendly societies or trade unions all under the designation of "approved societies", in Germany they are the old guilds, the unions and territorial units (Ortskrankenkassen).

We also show the maximum yearly income which entitles a workman to the benefits of insurance. Workmen between 16-70 years of age earning below or the maximum of \$1,250 per year in Great Britain or \$900 in Germany are insurable under the law. In Vienna there is no income limit. Every worker, servant or apprentice comes under the provisions of the Act.

We also show the yearly capitation or deduction from the pay envelope of every workman in order to obtain insurance.

In Great Britain the care of the dependents of the insured is not included. In Germany it is included but the yearly capitation is accordingly higher.

Table V illustrates the disbursing and adminis-

TABLE IV
ORGANIZATION

Country	Income (Yearly) of Insured	Yearly Capitation	Families of Insured	Number of Funds
Great Britain	£250 = \$1,250	9s. = \$2.25	Not included	7,876 (Approved societies and their branches)
Germany	M 3,600 = \$900	M 23 = \$5.25	Included (Territorial Funds)	7,500 (200 in Berlin)
Austria	No income limit for workers, servants or apprentices	Sch. 15 about \$2.00	Not included except: railroad and gov- ernment employees	82 (Law 1928-1929) includes railroad as- sociations

trative units of Great Britain. They are called Insurance Committees and are under the control of the Ministry of Health. Each insurance committee is subdivided into different smaller groups

schein" or sickness slip must be purchased. This costs about 12 cents and has reduced considerably the number of applications for treatment. It was also intended to act in such way.

TABLE V
ADMINISTRATION OF INSURANCE IN GREAT BRITAIN

INSURANCE COMMITTEES (about 200) Composed of Representatives of	{ County Council representing insured population. (Majority.) Panel Physicians Ministry of Health
INSURANCE COMMITTEES Subdivided into	{ Medical Service Sub-Committee (Equal number of doctors and laymen). (For complaints.) Panel Committee (For professional matters). Allocation Committee (Equal number of doctors and laymen).

whose composition and attributes are briefly outlined.

Table VI deals with the administration of insurance in Germany. The supervision rests with the department of labor. The most important units are the territorial funds: Ortskrankenkassen. They make all disbursements of sick benefits and pay the doctors through the medium of the Physicians' Union (Aerzteverband).

The other independent agencies or units had their own mode of payment, but since January 1932 all the funds use the medium of the Aerzteverband and have changed to the type of the Ortskrankenkassen. They employ general practitioners as well as specialists, have referees or "Vertrauensärzte" to check the work of physicians, employ technicians for physiotherapy and laboratory work and take care of hospitalization or transfer to sanatoria, convalescent homes, etc. They also supply optometric and orthopedic appliances as well as drugs and all means of therapy. The clerical, technical and administrative force equals or surpasses the number of medical employees.

For each single case of sickness a "Kranken-

GERMANY

(Supervision Department of Labor)

Territorial Funds (Ortskrankenkassen)	{ Pay physician through medium of Physicians' Union.
Trades Funds Mutual Aid Funds Leipsiger Verband (Voluntary)	{ Pay physician directly (per contract).* M: 1.80 per Krankenschein.— The Krankenschein is valid 1 month.— Unusual procedures like minor surgery, intravenous medication, are paid separately.

* Since January 1932, all the funds use the Aerzte Verband as intermediary for payment.

In Table VII we show the scale and period of sickness benefits in several countries. They are about alike and correspond to the degree of economic wants of each nation, figured at the lowest level of subsistence. The most liberal or advanced is here also represented by poor but socialistic Vienna.

Results for the Insured and for the Physician
After almost 50 years of social insurance in Germany and about 20 years in Great Britain we may well talk of results. We can see how many people are affected by this system and we can

work out the percentage of physicians absorbed by the system in the three countries, which we have chosen for our comparative study. We must not forget that besides compulsory insurance these countries have salaried positions for the

TABLE VII
SCALE AND PERIOD OF SICKNESS BENEFITS IN A FEW COUNTRIES

Country	Benefit Commences	Maximum Period of Benefit	Rate
Germany	Fourth day	26 weeks	50% of basic wage
Austria	First day	52 weeks	$\frac{3}{4}$ to $\frac{1}{2}$ of basic wage
Denmark	Fourth day	26 weeks in the course of a year	Minimum 40 ore
Great Britain	Fourth day	26 weeks	Males—15s per week Females—12s per week
Hungary	Third day	52 weeks	$\frac{3}{4}$ of basic wage
Norway	Fourth day	26 weeks	60% of basic wage
Poland	Third day	39 weeks	60% of basic wage
Switzerland	Third day	180 days	Minimum 1 fr per diem

From *Sickness Insurance in Europe* Commission on Medical Education

even fill roughly a ledger page with a credit and a debit side. Medical practitioners should not be thought of as a victimized group or as a separate class whose interests are opposed to the interests of the people at large. The famous G. B. Shaw held this view in his "Doctor's Dilemma."

If there was a grain of truth in the propounded thesis thus applied to the healer of old and not to the practitioner of modern medicine. The best interests of the physician coincide with the best interests of the people and the economic status of the physician mirrors the general situation. In Germany the doctor is a pauper not on account of the insurance system but because the entire middle class of professionals is starved and almost annihilated.

In Table VIII we show the percentage of the population affected by compulsory insurance. We have taken again for comparison Germany, Great Britain and Austria and we have added Sweden a sparsely settled and mostly agricultural country, which although highly cultured and advanced is placed only for the effect of contrast.

TABLE VIII
POPULATION AFFECTED BY INSURANCE

Country	Percentage of Population (Large cities up to 90%)	Of Occupied Population	Of Employed Population
Germany	62%	63%	77%
Austria			100%
Great Britain	35%	78%	86%
Sweden	16%		

Table IX represents the number of physicians employed under Social insurance and the average number of patients which come to the list of every employed physician. We have tried to

educational hospital and charitable functions of the State. In Germany and Austria there is not such a thing as an honorary position on a teaching, hospital, sanitation, government or municipal staff. We see therefore that only about 5% are wholly unemployed independent practitioners.

TABLE IX
NUMBER OF PHYSICIANS EMPLOYED BY SOCIAL INSURANCE
NUMBER OF PATIENTS PER PHYSICIANS LIST

Country	Total Number	Number Employed	Per Cent	Number of Patients per List
Great Britain	24,000	15,000	62%	Over 1,000 up to 2,500
Germany	47,000	38,000 to 39,000	80% to 95%	1,350 (Territorial Insurance) varying At present 600
Austria (Vienna)		441, including specialists		

Table X deals with the average income of physicians employed under insurance. We refer again to Great Britain, Germany and Austria, although they are widely divergent in their economic aspects. It brings out the fact that the income of the physician is dependent on the general economic status of each country and not on the form of his activity. In all these countries however it is reduced in comparison to the returns of independent practice. In Great Britain it is considerably higher than in Germany or Austria because of the better economic condition of the country at large.

On the other hand socialistic Vienna, which is the poorest of all, secures a higher remuneration

for its physicians solely in recognition of the physician's social usefulness and importance.

In Table XI we present a distinctive feature of the compulsory insurance system in continen-

system thus cultivating a defense mechanism wholly uncalled for. The free out-patient service of every hospital in London numbers from 40-60% of insured persons among its patronizers.

TABLE X
AVERAGE INCOME OF PHYSICIANS EMPLOYED BY INSURANCE

Country	No. of Patients	Families	Capitation	Number of Visits per Insured	Payment per Visit	Yearly Income from Insured	Yearly Income from Families	Yearly Income TOTAL
Great Britain	Over 1,000 Maximum 2,500	Optional	Yearly 9s. 6d. = \$2.37	Figured about 5 per year	About 2s. = \$0.50	About £400 = \$2,000	About £400 = \$2,000	£800 = \$4,000
Germany	1,350 average unlimited	Included	Yearly M:23 = \$5.25	About M:1.0 Home Call M:1.50	M:6,000 about \$1,500 In 40% M:1,000 = \$250	Included	M:6,000 = \$1,500
Austria (Vienna) (441 Physicians)	Optional except R.R. and Gov't Employees	Sch. 15 about \$2	Office Call Sch. 5 = \$0.70 Home Call Sch. 7.20 = \$1.00	Sch. 13,200 about \$1,900

tal Europe. It concerns hospitalization. In English-speaking countries hospitalization in city or State institutions is a development of the poor law concept. The hospital ward service is free and the physicians appointed hold honorary positions. They work there in order to acquire prestige and experience and to do their share in support of the destitute. In continental Europe they are salaried and have to devote their time either exclusively or for the most part to their hospital duties. Compulsory insurance pays ward or 3rd class service for a limited time for each insured and pays also the physician separately for each case. A price schedule for operation fees is mentioned not on account of its nominal character but to show the different conception of continental Europe, which does not ask the physicians to give something for nothing.

Table XII and Table XIII are a summation of the advantages and the disadvantages of the insurance system for the insured worker. An outstanding feature which results in a disadvantage of the insured is the changed relation between patient and physician. Any successful therapy requires a certain amount of confidence on the part of the patient. The insured worker is not yet adjusted to the practice of socialized medicine, he is distrustful and determined to beat the

TABLE XI
HOSPITALIZATION
PAID BY INSURANCE FUNDS—
THIRD CLASS OR WARD SERVICE

Germany	26 weeks	<i>Reichsgebührenordnung</i> Appendectomy M:20 = \$5 Gastro Intestinal Surgery M:40 = \$10 Tonsilectomy M:5 = \$1.25
Austria	From Sch. 50-250; \$7-\$35 Appendectomy 150 Sch. or \$21 Cataract 200 Sch. or \$28 G-I Surgery 250 Sch. or \$35

TABLE XII
RESULTS OF THE SYSTEM FOR THE INSURED

ADVANTAGES

1. Preserves the self respect of working people and prevents their being an object of charity.

- 2 Attention is given to minor ailments, thus enhancing preventative medicine
- 3 Patient is soon brought to the specialist and receives the benefit of modern medicine
- 4 Choice of physician, although limited, gives the patient independence
- 5 The quality of medical service is still superior to the former lodge or society practice

TABLE XIII

RESULTS OF THE SYSTEM FOR THE INSURED

DISADVANTAGES

- 1 The great number of patients per doctor impairs the physician's efficiency
- 2 The will to recuperate is impaired and malingering is rampant
- 3 Confidence in the doctor, who appears as a lowly and overburdened employee, is lessened (O P D favored)
- 4 Overprescribing and the abuse of physical therapy neurasthenize the patient and undermine his character
- 5 The patient acquires tendency to increase time of sickness and its ensuing benefits and compensations

Table XIV and Table XV summarize the advantages and the disadvantages of the insurance system for the physician as a class and as individuals. Aside of the changed economic aspects of the profession the most striking feature is the painful conflict between the new and the old order of things. The physician is harassed by an enormous amount of clerical work to which he can not get accustomed. He is more a scribe than a doctor. He is not any more a member of a free profession. The Insurance and its referees are a difficult boss and the patients are customers the harder to please the more they regard the doctor as a fellow worker like themselves. If a physician is condescending to patients and "easy" on certificates for all kinds of benefits he becomes a Kassenlöwe (Insurance lion), he is popular and a comparatively big earner, but he is also dishonest and a subject of contempt of his fellow practitioners. The only remedy in sight may be a fixed and graded salary for every physician employed.

TABLE XIV

RESULTS OF THE SYSTEM FOR THE PHYSICIAN

ADVANTAGES

- 1 The young graduate obtains sooner a practice and a modest livelihood
- 2 The practitioner is enabled to obtain for his patients the modern means of diagnosis and therapy
- 3 The free choice of physician although limited, favors display and success of personality
- 4 The system favors specialization (Germany)
- 5 Once employed the physician is more responsible to his own kind than to his client
- 6 His fees are determined his work and hours regulated. Vacations are obtainable
- 7 Panel practice is an object of sale (England)

TABLE XV

RESULTS OF THE SYSTEM FOR THE PHYSICIAN

DISADVANTAGES

- 1 Clerical work enormously increased
- 2 The individuality of the physician is submerged
- 3 The great number of daily callers prevents thorough examination and diagnosis. The work is mostly identification and sorting for institutions or specialists (Germany)
- 4 The relation between patient and doctor is often antagonistic. Condescendence to patients is a profitable abuse
- 5 The attitude of the patient is one of distrust
- 6 His medical activity is checked by superior authority (Referee or Kontrollärzte in Germany)
- 7 His income, although superior to club or lodge practice is definitely limited

Tendencies and Future Aspects of Health Insurance. The Social Insurance system comprises so many economical social and technical factors and so many possibilities of development and change that an appraisal of its present merits or its future aspects is almost impossible. One thing is quite certain: it is not a system of stability but one of eminent lability. Conflicting tendencies abound and general consent is still missing.

Concerning our subject Compulsory health insurance we find in Germany a tendency to centralize and unify the different funds to curtail the number of patients on the list of each doctor to stabilize the income of each employed physician and to extend institutionalization and specialization.

In Great Britain the medical profession seems to be more or less reconciled to the situation. Changes are advocated from different quarters and are different according to their point of view.

In Table XVI we have grouped the proposed changes according to their source and considered as authoritative the voice of organized medicine, of public agencies and of contemplated legislation. In this condensed manner we hope to present best the future aspects of the insurance system.

Table XVII concerns the municipality of Vienna which is the most advanced exponent of socialized medicine at present with the exception of Soviet Russia. Austria was reduced from an empire of 54,000,000 population to a small republic with 6,500,000 inhabitants. The different provinces of this small country have not changed much from pre-war days in regard to their social insurance. On the other hand the municipality of Vienna with less than 2,000,000 population has become autonomous and is administered by the socialist party. Under the leadership of the great scientist Prof. Dr. Tandler the city of Vienna has achieved the most ambitious and far-reaching social change. A magnificent city housing and building program has established about

Dominion of Canada: No report on health insurance would be complete if we omitted to mention the Dominion of Canada, a country on our continent, so very similar to our own in its economic and social aspects.—While Canada does not register yet a law of compulsory health insurance on its statutory books the question of socialization of the practice of medicine along continental European lines is much debated and proposed.

Table XVIII summarizes several aspects of health insurance in several parts of the Dominion.

TABLE XVIII
DOMINION OF CANADA

British Columbia:	Impending compulsory health insurance.
Saskatchewan:	Union hospitals supported by taxation—Small charges for service. Physicians on salary basis.
Alberta:	Travelling clinics—Employs salaried physicians.

Ontario: Proposed health insurance.
Canadian Medical Assn. (President, W. Harvey Smith)
Favors voluntary health insurance, organized, instituted and controlled by the medical profession.

Table XIX represents graphically the number of patients per physician in different leading countries. If service is to be considered as a commodity which has a "market" then we must admit that here also the law of demand and supply reigns supremely. Furthermore there is only one conclusion concerning the future economic status of the doctor in the United States whose lot is the smallest group of patients in the world. Of course other factors must be taken into account as for instance the use and demand for doctors. One thousand people in New York will need more medical service than perhaps 100,000 in Mississippi. Nevertheless figures have a definite significance.

CONCLUSIONS

1. Compulsory health insurance abroad is an unavoidable development of social and economic conditions.
2. It is an evolutionary step, beginning with mutual benefit organizations and contract practice, passing through the phase of voluntary health organizations and terminating with State control of a socialized medicine or State Medicine.
3. Its present insufficiencies prevail over the benefits it confers on the population.
4. The modern practice of medicine with its implicit high cost of diagnosis and therapy enhances socialized medicine and sentences to extinction the former individualistic practice.
5. A judicious and economically satisfactory form of salaried employment is the most desirable prospect for the profession.

TABLE XIX

NUMBER OF POPULATION PER PHYSICIAN

INTERNATIONAL DIGEST Oct. 1931

These conclusions were reached only concerning the situation abroad and have only a remote relation to conditions and future developments in our own country.

Individually we may foresee the extinction of the old family doctor and the end of the individualistic practice of medicine but as to the future of medicine we all may remain optimists.

Will this oldest and noblest profession be degraded by socialization and reduced economic returns? Will the single practitioner cease to be an altruist or a seeker of knowledge? We believe not. We are not worried over the loss of character on account of an alleged subdued individualism. We all know that the principle of differentiation, of individualization is a supreme biological urge in life. *It can not be damped.* And as long as there will be a physician there will be love of the profession, pride in workmanship, thirst for knowledge and that eternal human sympathy which, after all, fills the life of every one of us and prompts us to give to our patients the best there is in us, the best without stint and without reserve.

RADIUM POISONING

By FREDERICK B. FLINN, Ph.D., NEW YORK, N. Y.

From the College of Physicians & Surgeons, Columbia University, New York

THE term radium poisoning is used to differentiate between the effects produced when radium is used externally or in the form of implanted seeds or needles, and those resulting from its presence in the body through the ingestion per os, or injections of the element, or inhalation of radio-active dust.

When radium is used externally or in implanted seeds or needles the effects noted are those produced by Gamma rays and are the same as those which might result from exposure to α -rays. Part of the Gamma rays from radium have a shorter wave length and are harder than those of α -ray and have, therefore, a greater penetrating power. The danger from these rays is from overexposure either from too large a dosage or from a smaller dosage over a longer period of time. The harmfulness of so-called radium belts, —if they actually contain radium,—lies in this last exposure.

When radio-active material is absorbed by the body, it is transported by the blood stream and finally deposited in the skeleton in a more or less uniform manner because of its chemical similarity to calcium. There is no special concentration in any particular bone.

The first action of the radium, if not present in too large an amount, is a stimulation of the body functions. Diarrhœa may result and the quantity of urine passed temporarily increased if the dose is large enough. It is this laxative effect that is responsible for the subjective feeling of well being so often claimed for radium waters. When the radium is deposited in the bone, emanation,

a gas, is given off and carried around in the blood stream until finally eliminated by the lungs. The quantity of this emanation depends on the form in which the radium is deposited. Once deposited in the bone, the radium remains there indefinitely unless eliminated by medication, although there is an extremely small normal elimination over a period of years.

When the radium is absorbed into the body, the immediate surrounding tissue is subjected to a bombardment of Alpha and Beta particles as well as to Gamma rays. These Alpha and Beta particles are destructive to tissues under certain conditions. The Alpha particle is the most powerful physical agent known to man. This is partially understood when one realizes that a milligram of radium gives off 37 million Alpha particles per second for years, and might be likened to machine gun fire greatly magnified. The action may be stimulating at first, then destructive. Because of this stimulating action, the blood picture, except toward the terminal end, gives no indication of the exposure. A histological examination of the bone suggests a physical action similar to that of sand on rock,—fragmentation, absorption, and a replacement of the fragments by fibroid process. Due to stimulation of the osteoblasts and osteoclasts, bone proliferation may be seen in some instances in the same area as bone destruction is taking place. As bone-forming cells are overstimulated they gradually lose their function and bone healing or formation ceases. Spontaneous fractures occur and decalcification of bone is seen in radiographs. We are dealing,

in the jaw cases, with a partially devitalized bone which has become infected. It is impossible to stop the infection because of this damaged condition. It spreads rapidly, destroying the whole jaw and, if death does not occur from general septic condition and anemia, brain abscesses are apt to follow, of course ending fatally.

The change in the blood picture is due to the action of the radium on the bone marrow and lymph glands. Anemia and drop in white cells finally result and the drop in white cells may indicate the terminal end. The blood picture in humans varies somewhat during the clinical history, and in individual cases, so that there is no characteristic radium blood picture. Anisocytosis, polikilocytosis and nucleated red cells are frequently seen. The radium tends to shove the cells of the body back to the primitive cells, as is seen on histological examination of tissues. A certain percentage of the cases terminates in sarcoma, generally in cases where small amounts of radium have been present over a long period of time.

Because the blood picture is unreliable for the detection of radium poisoning, dependence must be placed on the electroscope. Two types of electroscopes are used to confirm the diagnosis. In making these tests the Gamma ray electroscope is placed near the back of the patient to

insure close proximity to large bone mass. The increased rate of leaf discharge over the normal rate gives an indication of the amount of radioactive material present. In the second test the patient blows the expired air through a drying train into an ionization chamber, and the radioactivity of the expired air, arising from the emanation carried in the blood stream, is determined. For details see the April and December numbers of the *American Journal of Roentgenology and Radium Therapy*, 1929.

Treatment: Operations are contra-indicated. In jaw cases the wound should be kept draining as freely as possible. Liver, iron injections, and blood transfusions do not show any permanent improvement in the blood picture. I have felt at times that the iron metabolism has been interfered with in these cases. Our best results have been from eating fruits, especially stewed apricots, which are high in iron and copper. High calcium therapy except when elimination is attempted. Our experience has indicated that if the patient be kept on from 20 to 30 drops of irradiate ergosterol three times a day there is an elimination over a long period of time. The difficulty lies in the fact that one is dealing with an already damaged bone condition and any intensive treatment will further decalcify the bones which lack the ability for regeneration.

Annual meeting, Hotel Statler, Buffalo, N. Y., May 23-25, 1932

THIS ISSUE OF THE JOURNAL

Careful preparation for the annual meeting of the Medical Society of the State of New York ensures smoothness and efficiency of the sessions. This issue of the Journal devotes 12 pages to the Program of the Annual Meeting, and 47 pages to the first installment of the annual reports of the officers and committees. The issue of May first will contain the remainder of the annual reports; and all the reports will be reprinted and

distributed to the members of the House of Delegates, who will be required to take official action on them.

No one could foretell the extent of the reports, although their size was anticipated because of the progressive activities of the State Society. The annual reports are therefore printed in two installments, thereby avoiding undue size and expense of the May first Journal.

SOCIALIZED OR STATE MEDICINE—PROFESSIONAL AND NATIONAL RESPONSIBILITY

Comments on Dr. Koffler's review of State medicine in Europe (page 437) by the Chairman of the Committee on Medical Economics of the Medical Society of the State of New York

Much vocal music resounds in Æsculapian halls. The prevailing Key is F (fear, fancy, fog, futuristic philosophy, futility). The tempo varies from *andante dolorosa* to *allegro furioso*. The climactic passages are full of major and minor chords with many dissonances. The score is broken abruptly before completion—for the end is not yet and none can relate the finale in words or music. However, the general theme is the medical treatment of persons under government compulsion and control, and the payment of some reward therefor, however small, to physicians for every service rendered.

Considerable imaginative unreliable fiction has been written about various phases of socialized medicine and compulsory health insurance in European and other countries, also libraries of reasonably reliable statistics and accounts of operation have been put forth.

No concise summation of this subject (in English) compares in value and in "over the page" interest with the account written by Dr. Emil Koffler appearing in this issue on page 437. The original presentation of this epitome and analysis was so clear that all physicians of this State and Country should have the privilege of surveying the subject through Dr. Koffler's masterly birds-eye view of a broad field of economic facts of profound importance to the peoples and our profession everywhere in the world.

The value of any governmental or social system is best determined by ascertaining its results to the whole of a people. The overwhelming evidence shows that the mental and moral fibre of the masses of workers is undermined or destroyed by compulsory health insurance. This destruction might very well be worse for any nation than prevalent disease entirely untreated. (See tables XII and XIII of Dr. Koffler's article.)

Confidence in a leader often brings signal success in any issue. If this system brings loss of confidence in the physician, the leader out of the wilderness of real illness is it good for the people? Do the people receive a just return for employers' and taxpayers' (and their own) money when the bulk of a trained physician's time must be used for completing sheaves of official papers? Does the encouragement and creation of malingerers add to the character and vigor of a nation? Can the morale of the sick be maintained or elevated when they are rushed and herded through multitudinous formalities without personal interest or individualized care? Can the cheapness of treatment under these systems in any way compensate

for the loss of discriminating care which even the poorest persons receive gratuitously in the United States?

We should never forget that the benefits to the people at large show what is the better or best in medical practice.

A secondary but important consideration is the effect of compulsory health insurance upon the great majority of physicians. Should specially trained scientists become, in the main, paper clerks? Should individuality in a highly educated man or woman be submerged in bureaucracy?—Should the preponderance of duties as a clerk prevent the specially-trained examiner from examining his patients? Should his office become a sorting spot for institutions or specialists with a prescription handed by guess work from one of a half-dozen prepared piles to the slightly ill or the malingerer? We are told that the relations of physicians and patients are often antagonistic and that condemnation to a patient's desires (for certificate of illness to secure money and avoid working) is a profitable and frequent abuse. Does this tend to elevate the practice of medicine for the benefit of the people? Again it is said that "the attitude of the patient is one of distrust." Does this enthuse the scientist whose elemental desire is to do good to others? Superior authority is a check upon his activity. How can he grow into fruitful scientific citizenship?

As a civic and State consideration the question of income from practice is of little importance. To the individual physician the question raised by Dr. Koffler's account is as follows: Which is to be preferred, a very small, certain, definitely limited income for a routine service long in prescribed hours and devoid of scientific opportunity, or uncertain but less limited income based entirely upon scientific attainments and willingness to work?

We do not share the fear voiced by many observers that European conditions of practice will soon be prevalent in America. Governmental tendencies (especially in States and large cities) do show increasing agencies for treating solvent prosperous earners free of all charge. (This has been made easy by the change of the title "Charity" into "Welfare.") This is the petty politician's way of exploiting medical practice to secure his "job" or promotion. (Why should he care what happens to the people or the nation after he is rich or gone?) Should this tendency advance extensively, the instinct of self-preservation is likely to prompt practitioners of medicine to demand an American system of compulsory health in

surance, instead of steadfastly opposing it, as now. However, they know (and they are the only ones who can possibly know all about it) that it would be bad for the people and bad for our Country.

The entire world needs the leadership of the United States in almost everything—especially in the complete, humane, individualized prac-

tice of medicine. *Merely thinking* of reducing benefits to the people and hurling the bulk of trained physicians into a hopeless clerical routine with an occasional spatter of empirical practice based on guess-work, is a violation of our duty as a nation. Who else than the United States is to lead the other nations back to the full enjoyment of complete service to the sick?

THE SCIENTIFIC PROGRAM

Whatever reason a doctor may have for attending the annual meeting of the Medical Society of the State of New York, he will expect a scientific program that is both interesting and practical. That printed on page 462 of this Journal has both of these qualities in a high degree.

A well-balanced scientific program consists of three elements:

1. Lectures
2. Exhibits
3. Clinics

The lecture meetings of the program recognize the fact that every physician,—specialist or family doctor,—is concerned with general conditions of the body. The afternoon sessions are therefore devoted to general topics, while the specialists will find their congenial places in the eight section meetings to be held on two mornings.

A doctor says that a paper is "practical" when

he can use it in treating his own cases. The Journal frequently receives requests from authors that they be permitted to publish their papers in journals of specialists. The editors anticipate the pleasure of publishing practically every paper on the program.

Modern medicine is founded on research and pathology. The scientific exhibit will afford a unique opportunity for family doctors to review their pathology and to see the methods used in research laboratories. The exhibits will be of special value because demonstrators will be in attendance to give personal demonstrations to visitors.

Contact with actual cases is the best form of medical teaching. A day of clinics will be conducted by medical leaders of Buffalo.

A physician attending the events listed in the scientific program will receive inspiration as well as instruction.

LOOKING BACKWARD

This Journal Twenty-five Years Ago

Pasteurization of Milk: Twenty-five years ago the question of the compulsory pasteurization of milk was widely debated. At that time pasteurization consisted in heating the milk to 167° F., and holding it at that point for half an hour.

This Journal of April, 1907, contains the following item on the action of the New York Academy of Medicine in regard to milk pasteurization:

"The Section on Public Health of the New York Academy of Medicine passed the following resolution at its meeting of March 12th, and the resolution was presented to the New York Academy of Medicine at its meeting on March 21st and adopted.

"(1) That the Section on Public Health of the New York Academy of Medicine does not believe in the necessity of the compulsory pasteurization of all of the milk supply of New York City, but recommends for the present to all those whose milk supply cannot be proven to be thoroughly inspected and wholesome, and mainly the

milk destined for the feeding of infants unless it is 'certified,' to boil their milk when delivered in the morning for three minutes.

"(2) That the health of the City of New York demands a persistence in the policy of supervision of farms, dairies, and creameries, supervision at the points of distribution in the City to the consumer, whether the milk that is distributed has been pasteurized or not.

"(3) That local and State health authorities and the Bureau of Animal Industry of the United States Department of Agriculture should cooperate with milk producers to prevent the occurrence of communicable diseases in cattle and their caretakers.

"(4) That the Section on Public Health recommends that the New York Academy of Medicine adopt the above resolutions, and that a copy be sent to the members of the Committee on Public Health of the Board of Aldermen, and to the Committee of the New York State Legislature having under consideration the Reece bill."

MEDICAL PROGRESS

The Simulation of Heart Disease.—K. Shirley Smith, writing in the *British Medical Journal* January 23, 1932, i, 3707, states that the three principal syndromes which may simulate heart disease are the effort syndrome, left mammary pain, chronic or paroxysmal, and retrosternal pain of muscular origin. The symptoms of effort syndrome are usually breathlessness, palpitation, dizziness, faintness and tightness or pain in the chest, provoked by effort often trivial in degree. The power of a given exertion to produce these symptoms varies very much from time to time. Conversely, in cardiovascular disease the predominant complaint is dyspnea, closely related to the degree of effort. The patient with organic heart disease feels quite well between bouts of dyspnea; with effort syndrome there is a background of other vague and indefinite sensations. Chronic left inframammary pain is often associated with respiratory troubles, which occur independently of effort, and are often relieved by it. A host of collateral symptoms frequently accompany left inframammary pain. This type of pain seldom afflicts men, and, when it does, it is generally the sequel to over-smoking. Paroxysmal left inframammary pain may simulate angina pectoris. If it is remembered that a wealth of subjective and objective phenomena speaks against angina, that the functional attacks mostly affect women at or before middle life, that amyl nitrite does not relieve neuropathic pain, that the pain of angina is usually constrictive and substernal, a mistaken diagnosis should rarely be made. Paroxysmal retrosternal pain is generally of cardiac origin, though some attacks may be attributed to muscular exhaustion. This may be suspected if thoracic respiration predominates over abdominal in the supine position, and if excessive tone or tenderness is found in the muscles in the neighborhood of the sternum. All patients of this group should receive careful investigation. In effort syndrome the basis of treatment lies in moral support and reassurance. The patient should be encouraged to take suitable normal healthy exercise in moderation. Faintness, giddiness, and syncope are often relieved by iron and strychnine. Ultra-nervous patients are helped by bromide and valerian. These general measures are also applicable in chronic left inframammary pain. Obesity, if present, must be dealt with. Thyroid extract, if employed, should be given in strictly moderate doses. The writer has seen angina pectoris precipi-

tated by its injudicious administration. In both chronic and paroxysmal inframammary pain, if tachycardia and restlessness are pronounced, luminal may prove helpful at night, with bromide and chloral twice daily in addition.

The Treatment of Paroxysmal Tachycardia.—On the basis of 17 personal cases, observed during a period of two years, Max Hochrein gives his experience with a prophylactic treatment of uncomplicated paroxysmal tachycardia in patients whose attacks could not be cut short by any of the usual methods, such as quinine, quinidine, strophanthin, or pilocarpine. By a combination of atropine with dietetic and psychotherapeutic measures he succeeded in preventing the appearance of attacks from the third to fifth day on, after the atropine had begun to take effect. Of the 17 individuals treated, 3 had a sinus, 13 an auriculoventricular, and one a ventricular, tachycardia. Three of the patients had been subject to attacks more than 15 years, and 6 for more than 5 years. Some of them had been having daily attacks. After these ceased, there was for the next 3 to 8 days an "uncertain" feeling about the heart, which disappeared with the further continuance of treatment. It is desirable to keep up the treatment for about 2 weeks after the attacks cease to appear. The value of the method was shown not only by the fact that the seizures stopped, but also by the fact that they had not returned, even in the case of individuals engaged in hard physical labor. One man who formerly had daily attacks had gone a year and a half without one, and a druggist who led quite a strenuous physical existence had been similarly free for a year. In our present ignorance of the etiology of tachycardia it is difficult to determine the mechanism by which atropine produces this result. It may be assumed that this substance exerts a favorable influence upon a heart in a condition of overexcitability by raising the threshold of irritability and lengthening the latent period. If the conception is true, that paroxysmal tachycardia develops on the basis of a vagotonia, the effect of atropine can be explained readily by its action upon the vagus, the fibers of which run to the sinus, the auriculoventricular node, and the ventricle. A special significance seems to attach to the inversion of the vagosympathetic balance, from which we must assume that this is brought up to a new level after the atropine has been

acting for some time, and that it becomes fixed there by some compensatory process even after administration of the drug has been stopped.—*Münchener medizinische Wochenschrift*, December 4, 1931.

The Heart in Diseases of the Respiratory Apparatus.—Circulation and respiration, says R. Siebeck, stand in a very close mutual relation, their functional activity being interdependent, and controlled by mechanical relations and strict regulation. We are very familiar with respiratory disturbances caused by cardiac insufficiency, but not so much is said about the effect of changes in the respiration upon the circulation and the activity of the heart. In the most various changes in the thorax, there is one common factor: Resistance in the channel of the lesser circulation is increased. From the laws of cardiac dynamics we must conclude that the right ventricle undergoes a "tonogenous" dilatation, and in the course of time hypertrophies. There is no doubt that diseases of the respiratory apparatus, especially emphysema, result in an increase of pressure in the pulmonary artery. The disease pictures are very characteristic: the patients are generally markedly cyanotic, the breathing is labored and dyspneic; when they are called upon for exertion, or often even when they are at rest, it is easy to recognize that these symptoms are more severe than the disturbances of respiration would lead one to expect. The roentgen examination is decisive for the evaluation of the size of the heart. Phenomena of obstruction appear after a time: first in the liver, with albuminuria and ascites prominent. The left ventricle becomes dilated, hypertrophic, and insufficient; the obstruction in the pulmonary circulation makes respiration more difficult, this puts a greater burden upon the right heart, and thus a vicious circle is established. The course in these cases is generally slow and chronic. The prognosis depends upon the changes in the lungs, and also upon the condition of the heart muscle. In treatment, the insufficiency can in the average case be overcome by rest and administration of digitalis. As expectorants, potassium iodide and ipecac are often beneficial. Obstinate coughing should if possible be controlled by a certain discipline, but if necessary medicaments may be used (codeine and the like). In compensated cases respiratory gymnastics are useful for increasing functional capacity. This aims not at a better movement of the thorax, but at a general invigoration, through which the patient learns a better respiratory technique.—*Münchener medizinische Wochenschrift*, February 5, 1932.

Comparative Study of Antiseptics in Experimentally Produced Local Infections.—Eli Saleeby and Malcolm J. Harkins undertook this study to determine the antiseptic most

suitable for the treatment of local wounds. Abscesses were produced in guinea-pigs with a recently isolated culture of *Staphylococcus aureus* and were then subjected to treatment by various germicides. All the abscesses treated with mercurophen, 1 and 2 per cent, healed in a maximum time of eleven days. The abscess treated with metaphen, 1:500 solution, and tincture of iodine, required fifteen days for complete healing. The animals treated with mercurochrome, 2 per cent solution, required a longer period to heal, seventeen and eighteen days. In the control animals wounds healed in from fifteen to sixteen days. It was observed that mercurophen was as efficient in 1 per cent as in 2 per cent solution. Also, there was practically no difference in the wounds of those guinea-pigs treated with the weaker solution of mercurophen (1:500) and with metaphen (1:500) solution. Compared with 2 per cent mercurochrome and tincture of iodine, both mercurophen and metaphen (1:500) solutions were superior. Although the local application of some of these antiseptics was of value, the writers believe that the mechanical cleansing and free drainage of the wound are more important factors in the healing process than the mere application of antiseptic solutions to already infected wounds.—*Annals of Surgery*, February, 1932, xcv, 2.

Pituitary Extract in the Treatment of Hyperchlorhydria and Gastroduodenal Ulcer.—P. L. Drouet and J. Simonin, in a paper read before the Paris Academy of Medicine, (*Bulletin de l'Académie de Médecine* of January 5, 1932), say that they have had occasion to observe the brilliant effects of pituitary extract (posterior lobe) upon gastric hyperacidity. They were led to make a systematic study of its action after one of them, while attending a patient suffering with diabetes insipidus and duodenal ulcer, accompanied by striking hypersecretion of gastric juice, had been in a position to note the striking improvement produced by injection of the extract. On a basis of 9 cases (4 of hyperchlorhydria, 4 of gastric ulcer and 1 of duodenal ulcer), they have demonstrated that this substance has the definite effect of diminishing gastric acidity, and that it brings considerable relief to patients suffering from this disagreeable functional disturbance. In every case from 12 to 20 daily injections of the extract were administered subcutaneously. Moreover, the close relationship between hyperacidity and gastroduodenal ulcer justifies the attempt to utilize this extract in the treatment of ulcers. It is possible in a relatively short time, as one of the cases demonstrates, to cure an ulcer not only clinically but also roentgenologically, without the aid of any other

medication, and subject only to certain dietary restrictions.

Multiple Malignant Growths of the Buccal Cavity.—Lord Moynihan's report of a case of primary carcinoma developing, at intervals, in three different parts of the buccal cavity (*The Lancet*, Jan. 2, 1932) and his statement that he had "never before seen two primary malignant growths in the mouth" prompts J. Bagot Oldham to report the following case. The patient, a man aged 62 years, had an epithelioma of the left floor of the mouth and alveolus, which was apparently cured by radium applications. He returned some six months later for re-examination when an indurated and ulcerated plaque showing the characteristics of epithelioma was found on the floor of the mouth on the right side. Oldham recalls that he reported a case similar to that of Lord Moynihan in *The Lancet* of October 26th, 1929. He also refers to twelve additional cases in the literature. These examples suggest that cases of this kind, though uncommon, occur more frequently than is generally supposed. They raise the question as to whether multiple primary tumors are produced by metastasis or implantation. Oldham considers it highly improbable that multiple buccal carcinomata can be explained as examples of metastasis, for though epithelioma of the tongue shows an almost constant invasion of the lymphatic glands, secondary deposits elsewhere are extremely rare. Over 250 years ago, Tulpius, the Dutch anatomist, said: "Cancer is just as contagious as inflammation of the eyes." Doubtless this is an exaggeration, but there are striking examples showing the spread of cancer from one part of the body to another and occasionally from host to host. Macewen tells of a man with an epitheliomatous ulcer of the lip, who had contracted the habit of rubbing the ulcer and then the tip of his nose with the same finger. Twenty months after the removal of the growth on the lip, he returned with a large ulcer on the tip of the nose identical microscopically with the original tumor. There is no doubt that implantation carcinoma of the alimentary canal has occurred on many occasions and that traumatized tissues are an especially fertile bed for this development. After citing additional instances of implantation cancer, Oldham expresses the opinion that the case which he reported, in which carcinoma developed in the tooth sockets, was doubtless another example of auto-inoculation or implantation.—*The Lancet*, January 23, 1932, ccxxii, 5656.

Modifications in the Blood Immediately Following Pneumothorax.—G. Ferrari points out

in the *Riforma medica* of January 2, 1932, that the modern view with reference to the action of pneumothorax is that it not only causes mechanical and circulatory modifications, but also has a far-reaching and complex biological effect through the humoral pathways, causing a certain amount of nonspecific protein substances to enter the circulation, and, with them, certain tuberculin substances capable of producing a sudden and profound stimulation in the blood constitution and in the tissues irrigated. Carrying out some studies of his own with reference to the physico-chemical characteristics of the blood following pneumothorax, he, like other authors, found that the number of leucocytes, the blood pressure and the refraction index after pneumothorax present constantly the same modifications that are observed in hemoclastic crises: decrease of leucocytes, lowering of the index of refraction, and modifications of color. These symptoms are in no way different after a recent pneumothorax and after an old one. The color of the venous blood, possibly because of the special influence of oxidation, presents a peculiar behavior, becoming first dark, then slightly redder, but the differences are as a rule slight and inconstant, the intensity of the reddening bearing no relation to the degree of lowering of the refraction index or to the increased leucopenia. The author's hope that the suspected passage of antigens set up by the "compression of the lung" would be revealed as the cause of characteristic modifications of the rapidity of sedimentation was doomed to disappointment, for there were no clear and unequivocal results demonstrating a disturbance of colloidal equilibrium. Nothing can as yet be stated with certainty with reference to the mechanism by which pneumothorax lets loose the succession of modifications, but the author points out the facility with which colloidoclastic modifications occur in tuberculous individuals upon slight provocation. It may be supposed that the passage into the blood of the products of disintegration of the protein molecule depends upon various stimuli which, through vasomotor modifications, have a special capacity for acting around diseased foci, where there is probably a particular vascular lability due to disintegration of the tissues. This would explain why in opposite mechanical phenomena (compression in pneumothorax, decompression in thoracentesis) the organism sometimes presents the same reactions.

Contraindications to Winter Climate as a Therapeutic Measure.—While there are few contraindications to a well conducted winter cure, it is nevertheless true, says W. Nonnenbruch, in the *Deutsche medizinische Wochen-*

schrift of December 4, 1931, that high mountain air is overstimulating for certain classes of patients. Tuberculous subjects with fresh infiltrations are known to progress better at moderate elevations than in mountains of great height. Cases complicated with laryngitis should not be sent to the high elevations. The stimulating qualities of the atmosphere at these heights are greater than lower down on the slopes, and are an advantage or a detriment according to the individual case. The condition of the circulation in certain severe types of hyperthyroidism offers a contraindication to a stay among the lofty mountains. This is true too of severe cases of Graves' disease with dilatation of the heart and arrhythmia perpetua. From hyperthyroid subjects it is only a step to the large group of nervous invalids with labile vegetative system, who frequently are sent to mountain climates in the winter to recover their health. One should remember that this is a stimulation therapy, and that labile, weakened bodies and nerves must at first be treated with weak doses, or be denied them altogether. While the choice of a resort must be strictly individual, some of these patients should be sent instead to a warm, southern climate. Palpitation, insomnia and nervous irritability are some of the indications that the elevation is too high, or the effect of the atmosphere too intense. Again, the effect of the exposure in poorly heated trains and cold waiting-rooms is bad in cases of sensitive and elderly nervous invalids. Persons with circulatory disturbances do better in the moderate climates. High blood pressure is a contraindication to high mountain sojourns. Cardiacs in a state of decompensation should avoid these places, as the thinness of the air and the increased metabolism lay too great a burden upon the heart. In all cases of organic disturbances of the heart and blood vessels these conditions are injurious and should be avoided.

Prognosis of Prostatic Enlargement.—Kenneth Walker, writing in *The Lancet*, December 12, 1931, ccxxi, 5650, states that enlargement of the prostate is nearly always progressive, but there may be long periods when the symptoms of enlargement may remain unaltered. Hence we have the question as to

whether future trouble should be anticipated by insisting on surgical intervention. In Walker's opinion an expectant attitude will not increase the risk when the evil day arrives, and in elderly men much may be gained by postponing drastic measures. While the possibility of malignancy, said to occur in some 15 per cent of seemingly innocent enlargement, should be borne in mind, this cannot be advanced as a complete justification of the wholesale removal of all enlarged prostates. Conservatism is further justifiable because, even in the best hands and with the most promising of patients, prostatectomy still remains an operation to which a very definite risk attaches, as is shown by mortality statistics in these cases. A number of factors affecting the mortality rate must be taken into consideration, *i.e.*, age, the presence of renal, cardiac, or pulmonary lesions, of diseases of the bowel or of diabetes, all of which increase the operative risk. With reference to function, the vast majority of patients can be promised that prostatectomy will be followed by complete restoration of function, unless the bladder wall has been irretrievably damaged by distention and sepsis, or a diverticulum exists. Complete restoration of the upper urinary passages is impossible in old and neglected cases. Lack of control is usually only a temporary inconvenience after suprapubic enucleation; there is greater danger of permanency after the perineal operation. Loss of virility is also more common after perineal prostatectomy. Catheter life as a temporary expedient, or as a preliminary to operation, is an excellent treatment; but as a permanent measure it carries a high mortality. When the prostate is much enlarged, when the posterior urethra is tortuous and difficult to navigate, and when catheterization is followed by hemorrhage or accompanied by pain, there is little chance that instrumentation can be carried out for any length of time. A patient for whom prostatectomy is contraindicated is in a far better position as regards life with a permanent drain than when dependent on a catheter. The various forms of electrotherapy are more often palliative than curative. In the small, obstructive prostate surgical diathermy often affords relief when surgery carries too high a risk.

LEGAL

REPORT OF THE COUNSEL

By LORENZ J. BROSNAN, Esq.

Counsel, Medical Society of the State of New York

To the House of Delegates—

Gentlemen:

Your Counsel herewith submits his report of the activities of the Legal Department of the Medical Society of the State of New York for the period from March 1st, 1931 to and including February 29th, 1932.

The past year has been an exceedingly busy one, both in court and in consultation. The appended figures state mere conclusions and give no adequate picture of the amount of work involved or the responsibility assumed.

At the outset your Counsel wishes to acknowledge the splendid support accorded him by your officers, Committees and individual members of the Society with whom he has come in contact during the reporting period. It has been both a privilege and a pleasure to have served under your worthy President Dr. William D. Johnson. Your Counsel wishes also to acknowledge the cooperation and helpful advice of your efficient Secretary Dr. Daniel S. Dougherty. Dr. Dougherty is known to you all. His calm judgment and sage counsel are given without reserve in the solution of your many problems. Your Counsel wishes also to express his appreciation for the cooperation afforded him by the members of your Insurance Committee comprising your Speaker Dr. John A. Card as Chairman, your President-Elect Dr. Charles Gordon Heyd and your Treasurer Dr. Frederic E. Sondern. Your Counsel has greatly enjoyed his relations with the members of your various Committees with whom, at one time or another, he has been in conference and consultation.

During the recording period "Courts and Doctors" by Lloyd Paul Stryker made its appearance. It won the instant approbation of the profession. It fills a long-felt want and should be owned and read by every member of the Society.

In making his report, your Counsel adheres to the convenient category employed in previous years whereby his activities have been divided into three main divisions: (a) the actual handling of malpractice actions before courts and juries and in the appellate tribunals; (b) counsel work with officers, Committees and individual members of the Society; and (c) legislative advice and activities.

Litigation

There is little to be said under this category that has not been written and said many, many times by your present Counsel and his predecessors. We again wish to repeat that the practice of medicine and surgery is an extra-hazardous profession, and that the rights of the physician in the courts are passed upon not by twelve members of his own profession but by twelve ordinary laymen who know little or nothing of medicine or surgery. The possibility of a malpractice suit is a very real danger to the active practitioner. No physician, eminent or lowly, specialist or general practitioner, is immune from attack.

Unless a physician has actually been sued, he cannot have even an incomplete understanding of the nature of the legal work involved in his defense. To translate complicated questions of medicine into language that will be understood by the average lay jury, to successfully convince jurors that a physician is working with factors over which often he has no control, to bring about a sympathetic understanding by our courts and judges of the problems of the active practitioner, to protect and zealously guard the good name of a physician in a malpractice action, is the work of your Counsel in the field of litigation, but it is only part of his work even in that field. To plan and supervise the necessary work in preparation for trial is equally important.

At this point the writer wishes to express his appreciation of the splendid work of his entire office staff and their fine spirit of devotion to duty which is responsible in no small measure for the results shown by this report.

From Table I it will be noted that in the past year 292 cases were instituted as compared with 286 in the previous year, representing an increase of only 6 cases. On the other hand, 227 cases were disposed of in the past year, as compared with 159 in the previous year. This means that 68 more cases were disposed of in the past year than in the previous year. This, however, does not take into consideration the fact that we were successful by negotiation in dissuading a large number of claimants or their attorneys from bringing actions in court. These figures also do not include a large number of claims still pending in which suit has not yet
